## 1 Preferences

Let $X$ be a metric space with metric $d: X \times X \rightarrow \mathbb{R}$. We say that $X$ is connected if it is not the disjoint union of two closed sets. A good example to keep in mind is $\mathbb{R}_{+}^{L}=\left\{\left(x_{1}, \ldots, x_{L}\right) \in\right.$ $\left.\mathbb{R}^{L}: x_{i} \geq 0\right\}$. Our interpretation for $X$ will usually be that of a consumption space, with each $x \in X$ a consumption bundle.

We will consider consumers that have preferences over $X$. A closed-contour preference on $X$ is a reflexive, transitive and complete binary relation $\leq$ such that for each $x \in X$ the upper contour set $\left\{x^{\prime} \in X: x \leq x^{\prime}\right\}$ and lower contour set $\left\{x^{\prime} \in X: x^{\prime} \leq x\right\}$ are closed subsets of $X$. We say that $\leq$ is a closed preference if it is a closed subset of $X \times X$; that is if $\left\{\left(x, x^{\prime}\right): x \leq x^{\prime}\right\}$ is a closed subset of $X \times X$. Every closed preference is closed-contour. To see this, suppose that $\leq$ is closed. Then the lower contour set $\left\{x^{\prime}: x^{\prime} \leq x\right\}=\left\{\left(w, w^{\prime}\right): w \leq w^{\prime}\right\} \cap X \times\{x\}$ is the intersection of two closed sets, and is therefore closed. The upper contour sets are also closed by an analogous argument.

We say that a preference $\leq$ on $X$ is represented by a function $u: X \rightarrow \mathbb{R}$ if $x \leq x^{\prime}$ iff $u(x) \leq u\left(x^{\prime}\right)$. We will refer to such functions as utility functions.

Claim 1.1. If $\leq$ is represented by a continuous $u: X \rightarrow \mathbb{R}$ then $\leq$ is closed.
Proof. Suppose $x_{n} \leq x_{n}^{\prime}$ for $n \in\{1,2, \ldots\}$. Then $u\left(x_{n}\right) \leq u\left(x_{n}^{\prime}\right)$. If the two sequences converge to $x$ and $x^{\prime}$ respectively, then $u(x) \leq u\left(x^{\prime}\right)$, and thus $\left\{\left(x, x^{\prime}\right): x \leq x^{\prime}\right\}$ is closed.

We say that a subset $Q \subseteq X$ is dense if for each $x \in X$ there is a sequence $\left(q_{n}\right)_{n}$ in $Q$ with $\lim _{n} q_{n}=x$. Equivalently, $X$ is equal to the closure of $Q$. Recall that $X$ is separable if it admits a countable dense subset. An example of separable metrix space is given by $\mathbb{R}^{L}$.

Theorem 1.2 (Debreu). For every closed-contour preference $\leq$ on a separable, connected metric space $X$ there is a continuous function $u: X \rightarrow \mathbb{R}$ that represents $\leq$.

An immediate corollary of this theorem is that a preference on a connected, separable metric space is closed if and only if it is closed-contour. We will henceforth assume that all preferences are closed (equivalently, contour-closed).

We say that a preference $\leq$ on a metric space $X$ is locally non-satiated (LNS) if for every $x \in X$ and $\varepsilon>0$ there is a $x^{\prime}$ such that $d\left(x, x^{\prime}\right)<\varepsilon$ and $x^{\prime}>x$. That is, every $x$ can be strictly improved by a small change.

Suppose now that $X$ is a subset of $\mathbb{R}^{L}$. We say that $\leq$ is convex if the upper contour set $\left\{x^{\prime}: x^{\prime} \geq x\right\}$ is convex for all $x \in X$. We say that it is strictly convex if $\lambda w+(1-\lambda) w^{\prime}>x$ whenever $w \succeq x, w^{\prime} \succeq x$, and $\lambda \in(0,1)$.

Claim 1.3. If $\leq$ is convex then $\left\{x^{\prime}: x^{\prime}>x\right\}$ is convex for all $x \in X$.
Suppose $X$ is convex. We will say that $\leq$ is convex* if

$$
\begin{equation*}
x^{\prime}>x \text { implies } \lambda x^{\prime}+(1-\lambda) x>x \text { for all } \lambda \in(0,1) . \tag{1.1}
\end{equation*}
$$

The property of being convex* has a simple interpretation: if $x^{\prime}$ is prefered to $x$, then moving in a straight line away from $x$ and towards $x^{\prime}$ results in an improvement.

Suppose that $\leq$ is represented by a utility $u$. What do convexity and convexity* mean for $u$ ? That is, what properties of $u$ correspond to these properties of $\leq$ ? Suppose that $X$ is convex. We say that $u: X \rightarrow \mathbb{R}$ is concave if for all $x, x^{\prime} \in X$ and $\lambda \in(0,1)$

$$
u\left(\lambda x+(1-\lambda) x^{\prime}\right) \geq \lambda u(x)+(1-\lambda) u\left(x^{\prime}\right) .
$$

We say that it is quasiconcave if

$$
\begin{equation*}
u\left(\lambda x+(1-\lambda) x^{\prime}\right) \geq \min \left\{u(x), u\left(x^{\prime}\right)\right\} \tag{1.2}
\end{equation*}
$$

Clearly, if $u$ is concave then it is quasiconcave, but not vice versa.
Claim 1.4. If $X$ is convex and $\leq$ is represented by $u: X \rightarrow \mathbb{R}$ then $\leq$ is convex if and only if $u$ is quasiconcave.

Proof. Assume that $u$ is quasiconcave, and suppose that $x^{\prime} \geq x$ and $x^{\prime \prime} \geq x$, so that $u\left(x^{\prime}\right) \geq u(x)$ and $u\left(x^{\prime \prime}\right) \geq u(x)$. By the quasiconcavity condition (1.2) $\hat{x}=\lambda x^{\prime}+(1-\lambda) x^{\prime \prime}$ satisfies $u(\hat{x}) \geq$ $\min \left\{u\left(x^{\prime}\right), u\left(x^{\prime \prime}\right)\right\} \geq u(x)$, and so $\hat{x} \geq x$. Thus $\leq$ is convex.

Assume now that $\leq$ is convex. Choose $x, x^{\prime} \in X$, and assume without loss of generality that $x \leq x^{\prime}$, i.e. $u(x) \leq u\left(x^{\prime}\right)$. Then by convexity $\hat{x}=\lambda x+(1-\lambda) x^{\prime}$ satisfies $\hat{x} \geq x$, and $u(\hat{x}) \geq$ $u(x)=\min \left\{u(x), u\left(x^{\prime}\right)\right\}$.

Claim 1.5. If $X$ is convex and $\leq$ is convex* and represented by $u$ then $u$ is quasiconcave.
Proof. Suppose not, so that the quasiconvavity condition is violated for some $x, x^{\prime}$ and $\lambda$. Denote $v(\alpha)=u\left(\alpha x+(1-\alpha) x^{\prime}\right)$, and assume without loss of generality that $v(0) \leq v(1)$. By assumption we have that $v(\lambda)<v(0)$. It follows from the continuity of $v$ that there is some $\beta \in(0, \lambda)$ such that $v(\lambda)<v(\beta)<v(0) \leq v(1)$. But since $\lambda \in(\beta, 1)$, it follows from (1.1) that $v(\lambda)>v(\beta)$, and we have reached a contradiction.

This claim in particular implies that for convex $X$, convexity* implies convexity. The next claim implies that the opposite implication is not true in general.

Claim 1.6. Suppose $X$ is convex, $\leq i s$ convex*, and for every $x \in X$ there exists $x^{\prime} \in X$ with $x^{\prime}>x$. Then $\leq$ is LNS.

Proof. For each $x \in X$, let $x^{\prime}>x$. The sequence $x^{n}=\frac{n-1}{n} x+\frac{1}{n} x^{\prime}$ satisfies $x^{n}>x$ and intersects every ball around $x$.

## 2 Prices and consumer choice

We consider a setting with $L$ commodities $\{1, \ldots, L\}$. A consumption space $X$ is a subset of $\mathbb{R}^{L}$. Let $\leq$ be a preference on $X$.

A price vector $p$ is an element of $\mathbb{R}^{L}$. Given $p$ and wealth $w \in \mathbb{R}$, the choice set $X^{*}(p, w)$ is given by

$$
\begin{equation*}
X^{*}(p, w)=\left\{x \in X: p \cdot x \leq w \text { and }\left(p \cdot x^{\prime} \leq w \text { implies } x^{\prime} \leq x\right)\right\} . \tag{2.1}
\end{equation*}
$$

Equivalently, $X^{*}(p, w)=\left\{x \in X: p \cdot x \leq w\right.$ and $\left(x^{\prime}>x\right.$ implies $\left.\left.p \cdot x^{\prime}>w\right)\right\}$. That is, if a bundle $x$ is in $X^{*}$ it is affordable, and bundles that are better than $x$ are not affordable. Note that it is possible that there are other bundles that are as desirable as $x$ and are affordable.

The next lemma shows that under LNS preferences, when $x$ is chosen, then any $x^{\prime}$ that is at least as good as $x$ must cost at least as much as $x$. Equivalently, if something costs less than $x$ then it is not as good.

Lemma 2.1. Suppose $\leq$ is LNS, and $x^{*} \in X^{*}(p, w)$. Then $x \geq x^{*}$ implies $p \cdot x \geq w$.
Proof. Suppose towards a contradiction that $x \succeq x^{*}$ and $p \cdot x<w$. Then there is some $\varepsilon$ small enough so that $p \cdot x^{\prime}<w$ for all $x^{\prime}$ such that $\left\|x-x^{\prime}\right\| \leq \varepsilon$. Since $\leq$ is LNS, there is some such $x^{\prime}$ such that $x^{\prime}>x$. Hence $x^{\prime}>x^{*}$, and so it is impossible that $x^{*} \in X^{*}(p, w)$.

Claim 2.2. Suppose $X$ is convex. Fix a price vector $p$ and $w \in \mathbb{R}$, and suppose that there is some $\hat{x} \in X$ with $p \cdot \hat{x}<w$. If for $x \in X$ with $p \cdot x \leq w$ it holds that $x^{\prime}>x$ implies $p \cdot x^{\prime} \geq w$, then $x \in X^{*}(p, w)$.

Proof. Let $x^{\prime}>x$. We need to show that $p \cdot x^{\prime}>w$. Suppose $p \cdot x^{\prime} \leq w$. Since $<$ is closed and $X$ is convex, for all $\lambda$ small enough it holds that $x^{\prime \prime}=(1-\lambda) x^{\prime}+\lambda \hat{x}>x$. But for $\lambda$ small enough it also holds that $p \cdot x^{\prime \prime}<w$, in contradiction to the claim hypothesis.

## 3 Production

In a setting with $L$ commodities, a production set $Y$ is a subset of $\mathbb{R}^{L}$. Given a price vector $p$, the optimal production set is

$$
\begin{equation*}
Y^{*}(p)=\left\{y \in Y: p \cdot y^{\prime} \leq p \cdot y \text { for all } y^{\prime} \in Y\right\} \tag{3.1}
\end{equation*}
$$

That is, $y$ is in $Y^{*}$ if it maximizes the payoff $p \cdot y$. The indirect utility is given by

$$
\begin{equation*}
v_{Y}(p)=\sup _{y \in Y} p \cdot y \tag{3.2}
\end{equation*}
$$

This is also known as the support function of $Y$. Note that if $Y^{*}(p)$ is non-empty then $v_{Y}(p)=p \cdot y$ for all $y \in Y^{*}(p)$.

For $\lambda \geq 0$, we denote $\lambda Y=\{\lambda y: y \in Y\}$. The Minkowski sum of two non-empty subsets $Y_{1}, Y_{2} \subseteq \mathbb{R}^{L}$ is given by $Y_{1}+Y_{2}=\left\{y_{1}+y_{2}: y_{1} \in Y_{1}, y_{2} \in Y_{2}\right\}$. It is easy to see that

1. $v_{\lambda Y}=\lambda v_{Y}$.
2. $v_{Y_{1}}+v_{Y_{2}}=v_{Y_{1}+Y_{2}}$.

The Minkowski sum of two closed sets is in general not closed. However, if $Y_{1}$ is open, then $Y_{1}+Y_{2}$ is open for every non-empty $Y_{2}$, since it is equal to the union of open sets $\bigcup_{y_{2} \in Y_{2}} Y_{1}+\left\{y_{2}\right\}$.

We denote Minkowski subtraction by

$$
Y_{1}-Y_{2}=\left\{y_{1}-y_{2}: y_{1} \in Y_{1}, y_{2} \in Y_{2}\right\} .
$$

Claim 3.1. Denote $Y=Y_{1}+\cdots+Y_{L}$. The following are equivalent:

1. $\sum_{j} y_{j} \in Y^{*}(p)$.
2. $y_{j} \in Y_{j}^{*}(p)$ for $j=1, \ldots, J$.

Fix some price vector $p$, and let $y \in Y^{*}(p)$. How does $y$ change when we change $p$ ? That is, if $y^{\prime} \in Y^{*}\left(p^{\prime}\right)$, what can we say about the relation between $y$ and $y^{\prime}$, given $p$ and $p^{\prime}$ ?

Claim 3.2. Let $y \in Y^{*}(p)$ and $y^{\prime} \in Y^{*}\left(p^{\prime}\right)$. Denote $\Delta y=y^{\prime}-y$ and $\Delta p=p^{\prime}-p$. Then

$$
\Delta p \cdot \Delta y \geq 0
$$

Proof. Since $p \cdot y^{\prime} \leq p \cdot y$ we have that

$$
p \cdot \Delta y \leq 0
$$

Likewise, $p^{\prime} \cdot y^{\prime} \geq p^{\prime} \cdot y$, and so

$$
p^{\prime} \cdot \Delta y \geq 0
$$

Subtracting the first from the second yields the desired result.

## 4 Private ownership economies and Walrasian equilibria

A private ownership economy consists of the following elements:

1. $L$ commodities.
2. $I$ consumers, each with a consumption set $X_{i} \subset \mathbb{R}^{L}$, a preference $\leq_{i}$ on $X_{i}$, and an endowment $e_{i} \in \mathbb{R}^{L}$.
3. $J$ firms, each with a production set $Y_{j}$.
4. Each consumer $i$ holds a stake $\theta_{i j}$ in firm $j$. We assume $\sum_{i} \theta_{i j}=1$ for all $j$.

An allocation is a pair $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ such that $x_{i} \in X_{i}, y_{j} \in Y_{j}$ and $\sum_{i} x_{i}=\sum_{i} e_{i}+\sum_{j} y_{j}$. The set of all allocations is denoted by $A$.

A Walrasian equilibrium consists of a price vector $p$ together with consumption vectors $\left(x_{i}\right)_{i}$ and production vectors $\left(y_{j}\right)_{j}$ such that

1. For all $i, x_{i} \in X_{i}^{*}\left(p, w_{i}\right)$, where $w_{i}=p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}$.
2. For all $j, y_{j} \in Y_{j}^{*}(p)$.
3. $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation.

We say that $\left(x_{i}\right)_{i}$ is Pareto optimal if there exists no allocation $\left(\left(x_{i}^{\prime}\right)_{i},\left(y_{i}^{\prime}\right)_{i}\right)$ such that $x_{i}^{\prime} \geq x_{i}$ for all $i$, and $x_{\ell}^{\prime}>x_{\ell}$ for some $\ell$.

Theorem 4.1 (First Welfare Theorem). Suppose each $\leq_{i}$ is LNS, and that $p$, $\left(x_{i}\right)_{i}$ and $\left(y_{j}\right)_{j}$ form an equilibrium. Then $x_{i}$ is Pareto optimal.

Proof. Suppose $x_{i}$ is not Pareto optimal. Then there exists an allocation $\left(\left(x_{i}^{\prime}\right)_{i},\left(y_{j}^{\prime}\right)_{j}\right)$ such that $x_{i}^{\prime} \geq x_{i}$ for all $i$, and $x_{\ell}^{\prime}>x_{\ell}$ for some $\ell$. Then, by the first equilibrium condition, $p \cdot x_{\ell}^{\prime}>$ $w_{i}$, and by Lemma 2.1, $p \cdot x_{i}^{\prime} \geq w_{i}$ for all $i$. Thus

$$
\sum_{i} p \cdot x_{i}^{\prime}>\sum_{i} w_{i} .
$$

Substituting the definition of $w_{i}$ yields

$$
\sum_{i} p \cdot x_{i}^{\prime}>\sum_{i}\left(p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}\right)
$$

Since $y_{j} \in Y_{j}^{*}(p)$, we know that $p \cdot y_{j} \geq p \cdot y_{j}^{\prime}$ by the second equilibrium condition, and so

$$
\sum_{i} p \cdot x_{i}^{\prime}>\sum_{i}\left(p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}^{\prime}\right) .
$$

Taking $p$ out of the parentheses yields

$$
p \cdot\left(\sum_{i} x_{i}^{\prime}\right)>p \cdot\left(\sum_{i}\left(e_{i}+\sum_{j} \theta_{i j} y_{j}^{\prime}\right)\right),
$$

and then changing the order of summation we arrive at

$$
p \cdot\left(\sum_{i} x_{i}^{\prime}\right)>p \cdot\left(\sum_{i} e_{i}+\sum_{j} y_{j}^{\prime} \sum_{i} \theta_{i j}\right) .
$$

Recall that $\sum_{i} \theta_{i j}=1$, and so

$$
p \cdot\left(\sum_{i} x_{i}^{\prime}\right)>p \cdot\left(\sum_{i} e_{i}+\sum_{j} y_{j}^{\prime}\right),
$$

which contradicts the assumption that $\left(\left(x_{i}^{\prime}\right)_{i},\left(y_{j}^{\prime}\right)_{j}\right)$ is an allocation.
Exercise: study a two commodity, two agent exchange economy using an Edgeworth box. Understand offer curves. See example of multiple equilibria and no equilibria.

## 5 Walrasian equilibria with transfers

A Walrasian equilibrium with transfers consists of a price vector $p$ and a transfers vector $t$, together with consumption vectors $\left(x_{i}\right)_{i}$ and production vectors $\left(y_{j}\right)_{j}$ such that

1. For all $i, x_{i} \in X_{i}^{*}\left(p, w_{i}\right)$, where $w_{i}=t_{i}+p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}$.
2. For all $j, y_{j} \in Y_{j}^{*}(p)$.
3. $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation.
4. $\sum_{i} t_{i}=0$.

A Walrasian quasi-equilibrium with transfers consists of a price vector $p$ and a transfers vector $t$, together with consumption vectors $\left(x_{i}\right)_{i}$ and production vectors $\left(y_{j}\right)_{j}$ such that

1. For all $i, p \cdot x_{i} \leq w_{i}$, and $x_{i}^{\prime}>_{i} x_{i}$ implies $p \cdot x_{i}^{\prime} \geq w_{i}$, where $w_{i}=t_{i}+p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}$.
2. For all $j, y_{j} \in Y_{j}^{*}(p)$.
3. $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation.
4. $\sum_{i} t_{i}=0$.

Theorem 5.1 (Second Welfare Theorem). Suppose that each $\leq_{i}$ is LNS and convex, each $X_{i}$ and $Y_{j}$ is convex, $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation, and that $\left(x_{i}\right)_{i}$ is Pareto optimal. Then there exists a price vector $p$ and a transfer vector $t$ such that $p, t,\left(x_{i}\right)_{i}$ and $\left(y_{j}\right)_{j}$ form a quasiequilibrium with transfers, and an equilibrium under the additional assumption that each $x_{i}$ is in the interior of $X_{i}$.

Proof. Denote $x=\sum_{i} x_{i}, y=\sum_{j} y_{j}$ and $e=\sum_{i} e_{i}$. Let $X_{i}^{+}=\left\{x_{i}^{\prime}: x_{i}^{\prime}>x_{i}\right\}$. Note that this is a non-empty set since $\leq_{i}$ is LNS, an open set since $\leq$ is closed, and a convex set, by Claim 1.3. Denote

$$
X^{+}=\sum_{i} X_{i}^{+} .
$$

As a Minkowski sum of convex sets, $X^{+}$is also convex. Furthermore, as a sum of open sets it is open.

Likewise, denote

$$
\hat{Y}=\{e\}+\sum_{j} Y_{j},
$$

and note that $\hat{Y}$ is convex.
We claim that $X^{+}$and $\hat{Y}$ are disjoint. Suppose not, so that there is some $\left(x_{i}^{+}\right)_{i}$ and $\left(y_{j}\right)_{j}$ such that $\sum_{i} x_{i}^{+}=e+\sum_{j} y_{j}$. But then this is an allocation with consumptions that strictly dominates $\left(x_{i}\right)_{i}$ for each $i$, which contradicts the assumption that $\left(x_{i}\right)_{i}$ is Pareto optimal.

It follows that by the Separating Hyperplane Theorem there is some (nonzero) price vector $p \in \mathbb{R}^{L}$ and a $w \in \mathbb{R}$ such that $p \cdot(e+y) \leq w$ for all $e+y \in \hat{Y}$ and such that $p \cdot x^{+}>w$ for all $x^{+} \in X^{+}$. Fix some such $p$. Note that $x \in \hat{Y}$, since $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation. Hence $p \cdot x \leq w$. On the other hand, by LNS, $x$ is in the closure of $X^{+}$and so $p \cdot x \geq w$. We thus have that $w=p \cdot x$. Since $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation, $w=p \cdot(e+y)$.

We claim first that $y_{j} \in Y_{j}^{*}(p)$ for all $j$. By Claim 3.1, this is equivalent to $p \cdot y^{\prime} \leq p \cdot y$ for any $y^{\prime} \in \sum_{j} Y_{j}$. This in turn is equivalent to $p \cdot\left(e+y^{\prime}\right) \leq p \cdot(e+y)=w$, which we have already shown above.

Let

$$
t_{i}=p \cdot x_{i}-\left(p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}\right)
$$

Then

$$
\sum t_{i}=p \cdot x-\left(p \cdot e+\sum_{i} \sum_{j} \theta_{i j} p \cdot y_{j}\right)=p \cdot x-\left(p \cdot e+\sum_{j} p \cdot y_{j}\right)=0
$$

where the first equality is a substitution of the definitions of $x$ and $e$, the second a consequence of $\sum_{i} \theta_{i j}=1$, and the third follows because $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an allocation.

By our definition of $t_{i}, p \cdot x_{i}=w_{i}$. To show that we have constructed a quasi-equilibrium we show that if $x_{i}^{\prime}>_{i} x_{i}$ then $p \cdot x_{i}^{\prime} \geq w_{i}$. Suppose towards a contradiction that there is an $x_{\ell}^{+} \in X_{\ell}$ such that $x_{\ell}^{+}>_{\ell} x_{\ell}$ and $p \cdot x_{\ell}^{+}<w_{\ell}-\varepsilon$ for some $\varepsilon>0$. By LNS, we can find for each $i \neq \ell$ an $x_{i}^{+} \in X_{i}$ such that $x_{i}^{+}>_{i} x_{i}$ and $p \cdot x_{i}^{+}<w_{i}+\varepsilon / I$. It follows that

$$
p \cdot \sum_{i} x_{i}^{+}<p \cdot \sum_{i} x_{i} .
$$

Denote $x^{+}=\sum_{i} x_{i}^{+}$. Then $x^{+} \in X^{+}$, and yet $p \cdot x^{+}<p \cdot x=p \cdot e$, and so we have reached a contradiction. Thus we have constructed a quasi-equilibrium.

Finally, suppose that each $x_{i}$ is an interior point. Then for each $x_{i}$ there is an $\hat{x}_{i}$ such that $p \cdot \hat{x}_{i}<w_{i}$; here we used the fact that $p$ is nonzero. It thus follows from Claim 2.2 that $x_{i} \in X^{*}\left(p, w_{i}\right)$, and so we have an equilibrium.

## 6 Excess demand

Consider a private ownership economy. We denote $X=\sum_{i} X_{i}, Y=\sum_{j} Y_{j}$ and $\sum_{i} e_{i}=e$. Let $p$ be a price vector. Recall that consumer $i$ with wealth $w_{i}$ will consume a bundle in $X_{i}^{*}(p, w)$. Recall also that $Y_{j}^{*}(p)$ is the set of all $y_{j}^{*} \in Y_{j}$ that maximize $p \cdot y_{j}$. Note that $p \cdot y_{j}^{*}=p \cdot \bar{y}_{j}^{*}$ for all $y_{j}^{*}, \bar{y}_{j}^{*} \in Y_{j}^{*}(p)$, and so $p \cdot Y_{j}^{*}(p)$ is well defined, as long as $Y_{j}^{*}(p)$ is non-empty. The wealth of consumer $i$ depends on $p$ and is given by

$$
w_{i}(p)=p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot Y_{j}^{*}(p) .
$$

The set of optimal consumption bundles can thus be written as depending on $p$ alone:

$$
X_{i}^{*}(p)=X_{i}^{*}\left(p, w_{i}(p)\right)
$$

Let

$$
X^{*}(p)=\sum_{i} X_{i}^{*}(p) \text { and } Y^{*}(p)=\sum_{j} Y_{j}^{*}(p) .
$$

We define the excess demand at price $p$ by

$$
Z^{*}(p)=X^{*}(p)-Y^{*}(p)-e .
$$

The excess demand at rice $p$ is a set of consumption bundles. Each corresponds to a possible total amount that is consumed at that price, in excess of the total available (produced plus endowed).

We note that for some $p$ either $X_{i}^{*}(p)$ or $Y_{j}^{*}(p)$ might be empty, in which case $Z^{*}(p)$ is also empty. We denote by $\mathscr{P}$ the set of prices for which $Z^{*}(p)$ is non-empty.

It is easy to see that if $t$ is a positive number, and if $p \in \mathscr{P}$, then $Z^{*}(t p)=Z^{*}(t)$. If all prices are multiplied by a positive constant then neither producers nor consumers change their behavior: $X_{i}^{*}(t p)=X_{i}^{*}(p)$ and $Y_{j}^{*}(t p)=Y_{j}^{*}(p)$. Thus also $Z^{*}(t p)=Z^{*}(p)$. A function or correspondence with this property is called homogeneous of degree zero.

Claim 6.1 (Walras's Law). $p \cdot z \leq 0$ for all $z \in Z^{*}(p)$. If we furthermore assume that each $\leq_{i}$ is LNS, then this holds with equality.

Proof. Let $z=\sum_{i} x_{i}^{*}-\sum_{j} y_{j}^{*}-\sum_{i} e_{i}$, with $x_{i}^{*} \in X_{i}^{*}(p)$ and $y_{j}^{*} \in Y_{j}^{*}(p)$. Then by the definition of $X_{i}^{*}$ we have that

$$
p \cdot x_{i}^{*} \leq w_{i}=p \cdot e_{i}+\sum_{j} \theta_{i j} p \cdot y_{j}^{*}(p) .
$$

Summing over $i$ yields

$$
p \cdot \sum_{i} x_{i}^{*} \leq p \cdot \sum_{i} e_{i}+\sum_{i} \sum_{j} \theta_{i j} p \cdot y_{j}^{*}(p) .
$$

Since $\sum_{i} \theta_{i j}=1$ for all $j$, this implies

$$
p \cdot \sum_{i} x_{i}^{*} \leq p \cdot \sum_{i} e_{i}+p \cdot \sum_{j} y_{j}^{*}(p)
$$

or

$$
p \cdot z \leq 0 .
$$

Finally, by Lemma 2.1, all the above inequalities hold with equality when each $\leq_{i}$ is LNS.

We say that there is free disposal if $Y$ contains $\mathbb{R}_{-}^{L}$.
Claim 6.2. If there is free disposal then $\mathscr{P} \subseteq \mathbb{R}_{+}^{L}$.
Proof. Choose any $p$ with $p_{\ell}<0$ for some commodity $\ell$, and let $y^{n} \in Y$ equal $-n$ in coordinate $\ell$, and vanish in the remaining coordinates. Then $p \cdot y^{n}=\left|p_{\ell}\right| \cdot n$, and so there is no $y^{*} \in Y$ that maximizes $p \cdot y$ in $Y$. Thus $Y^{*}(p)$ is empty, and so $Z^{*}(p)$ is empty.

Clearly, an equilibrium exists iff there is a $p$ such that $0 \in Z^{*}(p)$. The next claim shows that under some conditions, it suffices that $Z^{*}(p)$ has an element in $\mathbb{R}_{-}^{L}$.

Claim 6.3. If there is free disposal (i.e., $Y \supseteq \mathbb{R}_{-}^{L}$ ), if $Y$ is convex, and if each $\preceq_{i}$ is $L N S$, then an equilibrium exists iff there is a $p$ such that $Z^{*}(p)$ intersects $\mathbb{R}_{-}^{L}$.

Proof. If there is an equilibrium $p,\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}$ then $z=\sum_{i} x_{i}-\sum_{j} y_{j}-\sum_{i} e_{i}=0$ is in $Z^{*}(p)$, by definition. Hence $Z^{*}(p)$ intersects $\mathbb{R}_{-}^{L}$.

Suppose $z \in Z^{*}(p)$ and $z \in \mathbb{R}_{-}^{L}$, and write $z=x-y-e$, with $x=\sum_{i} x_{i}, x_{i} \in X_{i}^{*}\left(p, w_{i}(p)\right)$, and $y=\sum_{j} y_{j}, y_{j} \in Y_{j}^{*}(p)$. Let $y^{\prime}=y+z$, and note that $y^{\prime} \in Y$, since $Y \supseteq-\mathbb{R}^{L}$ and $Y$ is convex. By Claim 6.1, $p \cdot z=0$. Hence

$$
p \cdot y^{\prime}=p \cdot y+p \cdot z=p \cdot y
$$

and so $y^{\prime} \in Y^{*}(p)$. Let $z^{\prime}=x-y^{\prime}-e$, and note that $z^{\prime} \in Z^{*}(p)$. Finally,

$$
z^{\prime}=x-y^{\prime}-e=x-(y+z)-e=x-(y+x-y-e)-e=0 .
$$

Hence $p,\left(x_{i}\right)_{i}$ and $\left(y_{j}^{\prime}\right)_{j}$ form an equilibrium.

## 7 Compactifying the economy

Recall that an allocation $\left(\left(x_{i}\right)_{i},\left(y_{j}\right)_{j}\right)$ is an element of $\left(\prod_{i} X_{i}\right) \times\left(\prod_{j} Y_{k}\right)$ such that $\sum_{i} x_{i}=\sum_{i} e_{i}+$ $\sum_{j} y_{j}$, and that the set of all allocations is denoted by $A$.

Claim 7.1. Suppose that $Y \cap \mathbb{R}_{+}^{L}=\{0\}, Y \cap(-Y)=\{0\}, Y$ is convex and $X_{i} \subseteq \mathbb{R}_{+}^{L}$. Then $A$ is bounded.

Proof. Note that if $Y_{j}^{\prime}$ is a superset of $Y_{j}$ and $X_{i}^{\prime}$ is a superset of $X_{i}$, then the corresponding $A^{\prime}$ contains $A$. We can thus always enlarge $X_{i}$ and $Y_{j}$ without loss of generality. We will accordingly assume that $X_{i}=\mathbb{R}_{+}^{L}$ and that each $Y_{j}$ is a closed cone, by adding to it any elements of the form $\lambda y_{j}$, for $\lambda>0$ and $y_{j} \in Y_{j}$, and taking the closure.

Suppose towards a contradiction that for every $n$ we can find $a^{n}=\left(\left(x_{i}^{n}\right)_{i},\left(y_{j}^{n}\right)_{j}\right)$ such that $a^{n} \in A$ and

$$
\left\|a^{n}\right\|^{2}=\sum_{i}\left\|x_{i}^{n}\right\|^{2}+\sum_{j}\left\|y_{j}^{n}\right\|^{2}
$$

tends to infinity. Since each $X_{i}$ and $Y_{j}$ are cones,

$$
\hat{x}_{i}^{n}=x_{i}^{n} /\left\|a^{n}\right\| \quad \text { and } \quad \hat{y}_{i}^{n}=y_{j}^{n} /\left\|a^{n}\right\|
$$

are both also in $X_{i}$ and $Y_{j}$ respectively. The sequence $\hat{a}^{n}=\left(\left(\hat{x}_{i}^{n}\right)_{i},\left(\hat{y}_{j}^{n}\right)_{j}\right)$ of unit vectors has a converging subsequence, and so we assume without loss of generality that it converges to some unit vector $\hat{a}=\left(\left(\hat{x}_{i}\right)_{i},\left(\hat{y}_{j}\right)_{j}\right)$. Since $X_{i}$ and $Y_{j}$ are closed we have that $\hat{x}_{i} \in X_{i}$ and $\hat{y}_{j} \in Y_{j}$. Since $x^{n}-y^{n}=e, \hat{x}^{n}-\hat{y}^{n}=e /\|a\|$, and so $\hat{x}-\hat{y}=0$.

Since $Y \cap X=\{0\}$ we get that $\hat{x}=\hat{y}=0$. It follow immediately that $\hat{x}_{i}=0$ for all $i$. We claim that likewise $\hat{y}_{j}=0$ for all $j$. Otherwise, suppose $y_{\ell} \neq 0$. Then $\sum_{j \neq \ell} y_{j}=-y_{\ell}$. Since each $Y_{j}$ is a cone, $y_{\ell}$ and $-y_{\ell}$ are both in $Y$, in contradiction to the assumption that $Y \cap(-Y)=\{0\}$. We have thus shown that $\hat{a}=0$, in contradiction to the fact that $\hat{a}$ is a unit vector.

Proposition 7.2. Suppose that each $Y_{j}$ and $X_{i}$ is convex, each $\leq_{i}$ is convex*, and that $A$ is bounded. Let $K$ be a compact convex set whose interior contains A. Define a "hat" private ownership economy by $\hat{X}_{i}=K \cap X_{i}$ and $\hat{Y}_{i}=K \cap Y_{i}$, with all other elements remaining the same. Then every equilibrium of the hat economy is an equilibrium of the original economy.

Proof. Suppose $p,\left(\hat{x}_{i}\right)_{i}$ and $\left(\hat{y}_{i}\right)_{i}$ form an equilibrium of the hat economy. Clearly $\hat{x}=\hat{y}-e$, and so it remains to be shown that $\hat{x}_{i} \in X_{i}^{*}(p)$ and $\hat{y}_{j} \in Y_{j}^{*}(p)$.

Suppose $\hat{x}_{i} \notin X_{i}^{*}(p)$, so that there is some $x_{i} \in X_{i}$ such that $x_{i}>_{i} \hat{x}_{i}$ and $p \cdot x_{i} \leq w_{i}$. Since $\hat{x}_{i}$ is in the interior of $K$, it follows from the assumption that $X_{i}$ is convex that for $\lambda$ small enough $x_{i}^{\prime}:=\lambda x_{i}+(1-\lambda) \hat{x}_{i}$ is in $\hat{X}_{i}$. But then $x_{i}^{\prime}>_{i} \hat{x}$, since $\leq_{i}$ is convex*, while clearly $p \cdot x_{i}^{\prime} \leq w_{i}$. So $\hat{x}_{i} \notin \hat{X}_{i}^{*}(p)$.

Finally, suppose that $\hat{y}_{j} \notin Y_{j}^{*}(p)$. By an analogous argument there is some $y_{j}^{\prime} \in \hat{Y}_{j}$ such that $p \cdot y_{j}^{\prime}>p \cdot \hat{y}_{j}$, and so $\hat{y}_{j} \notin \hat{Y}_{j}^{*}(p)$.

## 8 Kakutani's Theorem and Debreu's Theorem

Let $A, B$ be subsets of $\mathbb{R}^{n}, \mathbb{R}^{m}$. A correspondence $\Gamma: A \rightarrow B$ is a map that assigns to each $a \in A$ a subset $\Gamma(a) \subseteq B$. We say that $\Gamma$ is nonempty / closed / convex if each $\Gamma(a)$ is nonempty / closed / convex.

A correspondence $\Gamma: A \rightarrow B$ is upper hemicontinuous at $a$ if for all $a_{n} \rightarrow a$ and $b_{n} \rightarrow b$ such that $b_{n} \in \Gamma\left(a_{n}\right)$ it holds that $b \in \Gamma(a)$. Note that this implies that $\Gamma(a)$ is closed for every $a$, by taking $a_{n}=a$. It is said to be upper-hemicontinuous if it is upper-hemicontinuous at all $a \in A$.

Claim 8.1. A correspondence $\Gamma: A \rightarrow B$ is upper hemicontinuous iff its graph $\{(a, b): b \in \Gamma(a)\}$ is a closed subset of $A \times B$.

Proof. Suppose $\Gamma$ is upper hemicontinuous, and consider a converging sequence ( $a_{n}, b_{n}$ ) $\rightarrow$ $(a, b)$ in its graph. Then upper hemicontinuity implies that $(a, b)$ is also in the graph. Hence the graph is closed.

Conversely, suppose the graph is closed, and consider $a_{n} \rightarrow a$ and $b_{n} \rightarrow b$ such that $b_{n} \in \Gamma\left(a_{n}\right)$. Since the graph is closed, $(a, b)$ is in the graph, i.e., $b \in \Gamma(a)$.

A fixed point of a correspondence $\Gamma: A \rightarrow A$ is $a \in A$ such that $a \in \Gamma(a)$.
Theorem 8.2 (Kakutani). Let $A$ be a compact convex subset of $\mathbb{R}^{n}$, and let $\Gamma: A \rightarrow A$ be a nonempty, upper-hemicontinuous, convex correspondence. Then $\Gamma$ has a fixed point.

Denote $\Delta_{L}=\left\{p \in \mathbb{R}_{+}^{L}: \sum_{\ell} p_{\ell}=1\right\}$. In the next claim we "forget" all we know about $Z^{*}$, and only assume what is explicitly written.

Theorem 8.3 (Debreu). Let $C$ be a compact convex subset of $\mathbb{R}^{L}$. Suppose that a correspondence $Z^{*}: \Delta_{L} \rightarrow C$ is nonempty, upper-hemicontinuous, convex, and satisfies $p \cdot z \leq 0$ for all $z \in Z^{*}(p)$. Then there is a $p \in \Delta_{L}$ and $a z \in Z^{*}(p)$ such that $z \in-\mathbb{R}^{L}$.

Proof. Define the correspondence $M: C \rightarrow \Delta_{L}$ by $M(z)=\operatorname{argmax}_{p} p \cdot z$. That is, $M(z)$ is the set of $p$ that maximize $p \cdot z$. Since $\Delta_{L}$ is compact and convex, it is easy to see that $M$ is upper-hemicontinuous, non-empty and convex.

Let $\Gamma: \Delta_{L} \times C \rightarrow \Delta_{L} \times C$ be the correspondence given by $\Gamma(p, z)=M(z) \times Z^{*}(p)$. It is again easy to see that the domain $\Delta_{L} \times C$ is compact and convex and that $\Gamma$ is nonempty, upperhemicontinuous and convex. Thus, by Kakutani's Theorem, it has a fixed point ( $p, z$ ). That is, there are $p$ and $z$ such that

$$
p \in M(z) \text { and } z \in Z^{*}(p) .
$$

Since $p \in M(z), p^{\prime} \cdot z \leq p \cdot z$ for any $p^{\prime} \in \Delta_{L}$. And since $z \in Z^{*}(p), p \cdot z \leq 0$. Hence $p^{\prime} \cdot z \leq 0$ for any $p \in \Delta_{L}$, and so $z \in \mathbb{R}_{-}^{L}$.

## 9 Existence of equilibria

To prove the existence of equilibria we will use Theorem 8.3. It requires compactness; that will be provided by Claim 7.1 and Proposition 7.2. It also requires upper-hemicontinuity.

Proposition 9.1. If $Y$ is compact then the correspondence $Y^{*}$ is upper-hemicontinuous.
Suppose furthermore that $Y$ is convex, each $X_{i}$ is compact and convex, each $\succeq_{i}$ is convex* and LNS, and $e_{i}$ is in the interior of $X_{i}$. Then the correspondence $Z^{*}$ is nonempty, uppersemicontinuous and convex.

Theorem 9.2. Suppose each $X_{i}$ is a closed, convex subset of $\mathbb{R}_{+}^{L}$, each $\succeq_{i}$ is convex* and LNS, each $e_{i}$ is in the interior of $X_{i}, Y \cap \mathbb{R}_{+}^{L}=\{0\}, Y \cap(-Y)=\{0\}, Y$ is convex, and there is free disposal. Then there exists an equilibrium.

Proof. By Claim $7.1 A$ is bounded. Hence by Proposition 7.2 any equilibrium of the hat economy is an equilibrium of the original economy. We can thus assume henceforth that each $X_{i}$ is compact, as is $Y$. By Proposition 9.1 the excess demand correspondence $Z^{*}$ is upper-hemicontinuous and convex. By Claim 6.1 it satisfies Walras's Law. We can therefore apply Theorem 8.3 to conclude that there is some $z \in R_{-}^{L}$ such that $z \in Z^{*}(p)$. Thus, by Claim 6.3 there exists an equilibrium.

## 10 Approximate equilibria

In this section we consider exchange economies, with $I$ consumers and $L$ goods, as usual. We will start by proving an existence theorem for equilibria, under strong conditions.
Theorem 10.1. Consider an exchange economy with each $X_{i}=[0, x]^{L}$ for some $x$, and with strictly monotone and convex preferences. Suppose also that each $e_{i}$ is in the interior of $X_{i}$. Then there exists an equilibrium with prices $p \gg 0$.

Proof. Recall that we denote $\Delta_{L}=\left\{p \in \mathbb{R}_{+}^{L}: \sum_{\ell} p_{\ell}=1\right\}$. For each $p \in \Delta_{L}$, the set of feasible consumption bundles $\left\{x_{i} \in X_{i}: p \cdot x_{i} \leq p \cdot e_{i}\right\}$ is compact and non-empty. Since preferences are convex and $X_{i}$ is compact, $X_{i}^{*}(p)=X_{i}^{*}(p, p \cdot w)$ is compact, convex, and non-empty, and so is the excess demand $Z^{*}(p)=\sum_{i} X_{i}^{*}(p)-\sum_{i} e_{i}$, which is furthermore upper-hemicontinuous since each $e_{i}$ is internal (see Proposition 9.1). Since preferences are strictly monotone they are LNS, and thus Walras's Law implies that $p \cdot z=0$ for all $z \in Z^{*}(p)$. By Theorem 8.3 there is a $p$ such that $Z^{*}(p) \cap \mathbb{R}_{-}^{L}$ is non-empty. Note that it must be that $p \gg 0$, since preferences are strictly monotone, and thus if $p_{\ell}=0$ for some commodity $\ell$ then $X_{i}^{*}(p)$ will only include elements in which the demand for good $\ell$ is equal to $x$ (i.e., the maximal possible), but then, since $e_{i}$ is internal, the demand for $\ell$ will exceed supply, and it would be impossible that $Z^{*}(p)$ includes elements of $\mathbb{R}_{-}^{L}$.

It follows that there are $\left(x_{i}\right)_{i}$ such that $x_{i} \in X_{i}^{*}(p)$, and $\sum_{i}\left(x_{i}-e_{i}\right) \in \mathbb{R}_{-}^{L}$. To finish the proof we show that this sum vanishes. Assume it does not. Then, since $p \gg 0, p \cdot \sum_{i}\left(x_{i}-e_{i}\right)<0$. But by LNS we know that $p \cdot x_{i}=p \cdot e_{i}$, and thus we have reached a contradiction.

An approximate equilibrium consists of a price vector $p$ together with consumption vectors $\left(x_{i}\right)_{i}$ such that

1. For all $i, p \cdot x_{i} \leq p \cdot e_{i}$.
2. For all $i$ except at most $L, x_{i} \in X_{i}^{*}\left(p, p \cdot e_{i}\right)$.
3. $\left(x_{i}\right)_{i}$ is an allocation: $\sum_{i} x_{i}=\sum_{i} e_{i}$.

Theorem 10.2. Consider an exchange economy with each $X_{i}=[0, x]^{L}$ for some $x$, and with strictly monotone preferences. Suppose also that each $e_{i}$ is in the interior of $X_{i}$. Then there exists an approximate equilibrium with prices $p \gg 0$.

The only difference between this Theorem and Theorem 10.1 is that there is no assumption that preferences are convex. This implies that there will not always be an equilibrium.

Proof of Theorem 10.2. By our assumptions $Z^{*}$ is a non-empty, compact correspondence, which is furthermore upper-hemicontinuous (see Proposition 9.1). However, since we have not assumed that preferences are convex, there will not necessarily be an equilibrium. I.e., there is not necessarily a price vector $p$ such that $0 \in Z^{*}(p)$. Denote by $Z_{c}^{*}(p)$ the convex hull of $Z^{*}(p)$. Then clearly $Z_{c}^{*}$ is a non-empty, compact, convex, upper-hemicontinuous correspondence. Thus, as in the proof of Theorem 10.1, there must exist a $p \gg 0$ such that $0 \in Z_{c}^{*}(p)$.

To finish the proof, we will need the following result, which we will prove later. We denote by $\operatorname{Conv}(A)$ the convex hull of a set $A$.
Lemma 10.3 (Shapley-Folkman). Let $A_{1}, \ldots, A_{K}$ be subsets of $\mathbb{R}^{L}$, and suppose that $x \in$ $\operatorname{Conv}\left(A_{1}+\cdots+A_{K}\right)$. Then there exist $a_{1}, \ldots, a_{k}$ such that

1. $a_{i} \in \operatorname{Conv}\left(A_{i}\right)$ for all $i$,
2. $a_{i} \in A_{i}$ for all but $L$ values of $i$,
3. $x=a_{1}+\cdots+a_{K}$.

Applying the lemma to $0 \in Z_{c}^{*}(p)=\sum_{i} X_{i}^{*}(p)-e_{i}$, we can conclude that there are $\left(z_{i}\right)_{i}$ such that

1. $z_{i} \in \operatorname{Conv}\left(X_{i}^{*}(p)-e_{i}\right)$.
2. $z_{i} \in X_{i}^{*}(p)-e_{i}$ for all but $L$ consumers $i$.
3. $0=\sum_{i} z_{i}$.

Denoting $x_{i}=z_{i}+e_{i}$, this implies that

1. $x_{i} \in \operatorname{Conv}\left(X_{i}^{*}(p)\right)$, and hence $p \cdot x_{i} \leq p \cdot e_{i}$.
2. $x_{i} \in X_{i}^{*}(p)$ for all but $L$ consumers $i$.
3. $\sum_{i} x_{i}=\sum_{i} e_{i}$.

Thus $\left(x_{i}\right)_{i}$ and $p$ form an approximate equilibrium.
We now turn to prove Lemma 10.3. This result is in fact a generalization of the Carathéodory Theorem for convex hulls.

Theorem 10.4 (Carathéodory). Suppose $a \in \operatorname{Conv}(A) \subseteq \mathbb{R}^{L}$. Then a is a convex combination of at most $L+1$ elements of $A$.

Proof. Suppose that $a$ is the convex combination $\sum_{\ell} \lambda_{\ell} a_{\ell}$ of $\left\{a_{1}, \ldots, a_{n}\right\} \subseteq A$, and that $n$ is the minimal such that is possible. In particular, this means that $\lambda_{\ell}>0$.

Define the linear map $\Phi: \mathbb{R}^{n} \rightarrow \mathbb{R}^{L} \times \mathbb{R}$ by

$$
\Phi\left(x_{1}, \ldots, x_{n}\right)=\left(\sum_{\ell} x_{\ell} a_{\ell}, \sum_{\ell} x_{\ell}\right) .
$$

The kernel of $\Phi$ (i.e., $\left.\left\{x \in \mathbb{R}^{n}: \Phi(x)=(0,0)\right\}\right)$ has dimension at least $n-(L+1)$. Assume towards a contradiction that $n>L+1$. Then this dimension is positive, and there is some nonzero $x \in \mathbb{R}^{K}$ such that $\sum_{\ell} x_{\ell} a_{\ell}=0=\sum_{\ell} x_{\ell}$. By multiplying $x$ by a constant we can furthermore
require that $(x+\lambda)_{\ell} \geq 0$ for all $i$ (since $\lambda \gg 0$ ) and that $(x+\lambda)_{\ell}=0$ for some $i$. Denote $\eta=x+\lambda$. Then

$$
\sum_{\ell} \eta_{\ell} a_{\ell}=\sum_{\ell} x_{\ell} a_{\ell}+\sum_{\ell} \lambda_{\ell} a_{\ell}=a
$$

and

$$
\sum_{\ell} \eta_{\ell}=\sum_{\ell} x_{\ell}+\sum_{\ell} \lambda_{\ell}=1
$$

so that $a$ is a convex combination of less than $n$ elements of $A$, and we have reached a contradiction.

Proof of Lemma 10.3. We note first that $\operatorname{Conv}\left(A_{1}+\cdots+A_{K}\right)=\operatorname{Conv}\left(A_{1}\right)+\cdots+\operatorname{Conv}\left(A_{K}\right)$. Thus $x=\sum_{i} a_{i}$ where $a_{i} \in \operatorname{Conv}\left(A_{i}\right)$. Suppose each $a_{i}$ is a convex combination $a_{i}=\lambda_{i, 1} a_{i, 1}+$ $\cdots+\lambda_{i, n_{i}} a_{i, n_{i}}$ of elements of $A_{i}$, and that this representation minimizes the total number of coefficients $n=\sum_{i} n_{i}$. This means that $\lambda_{i, j}>0$ for all $i, j$.

Define the linear map $\Phi: \mathbb{R}^{n_{1}} \times \cdots \times \mathbb{R}^{n_{K}} \rightarrow \mathbb{R}^{L} \times \mathbb{R}^{K}$ by

$$
\Phi\left(x_{1}, \ldots, x_{K}\right)=\left(\sum_{i} \sum_{\ell=1}^{n_{i}} x_{i, \ell} a_{i, \ell}, \sum_{\ell} x_{1, \ell}, \ldots, \sum_{\ell} x_{K, \ell}\right) .
$$

The kernel of $\Phi$ has dimension at least $n-(L+K)$. By an argument analogous to the one in Theorem 10.4 we conclude that $n \leq L+K$, as $n>L+K$ implies that there is some ( $x_{1}, \ldots, x_{K}$ ) such that

$$
\sum_{i} \sum_{\ell=1}^{n_{i}} x_{i, \ell} a_{i, \ell}=0=\sum_{\ell} x_{1, \ell}=\cdots=\sum_{\ell} x_{K, \ell},
$$

which, after multiplication by a constant can be added to $\lambda$ to yield convex combinations with a combined smaller support.

Finally, it follows from $n \leq L+K$ and the pigeon hole principle that there are at least $K-L$ values of $i$ such that $n_{i}=1$, and hence, for these $i, a_{i} \in A_{i}$.

A nice related theorem is the following.
Theorem 10.5 (Kirchberger). Let $A$ ("sheep") and B ("wolves") be finite subsets of $\mathbb{R}^{2}$. Suppose that for every $C \subseteq A \cup B$ of size 4 there is a line that strictly separates $A \cap C$ from $B \cap C$ (i.e., the sheep in $C$ can be separated from the wolves in $C$ by a straight fence). Then $A$ can be strictly separated by a line from $B$ (the sheep can be separated from the wolves by a straight fence).

## 11 Scitovsky contours

Consider an exchange economy with each $\succeq_{i}$ convex. The Scitovsky contour of $\left(x_{i}\right)_{i}$ is

$$
S\left(x_{1}, \ldots, x_{I}\right)=\sum_{i}\left\{x_{i}^{\prime}: x_{i}^{\prime} \geq_{i} x_{i}\right\}
$$

That is $S$ is the set of all total consumptions that can be decomposed into individual consumptions that are at least as good as $\left(x_{i}\right)_{i}$.

Suppose $\left(x_{i}\right)_{i}$ and $p$ form an equilibrium, so that $p \cdot x^{\prime} \geq p \cdot x$ for every $x^{\prime} \in S\left(x_{1}, \ldots, x_{I}\right)$. It follows that if $p \cdot x>p \cdot \hat{x}$ then, for any $\left(\hat{x}_{i}\right)_{i}$ such that $\hat{x}=\sum_{i} \hat{x}_{i}$, there must be some consumer $i$ for whom $x_{i}>_{i} \hat{x}_{i}$.

The lesson is that if current total consumption is $x$ and prices are at $p$, then an alternative total consumption $\hat{x}$ can be ruled out (on the grounds of making someone worse off) just by considering the value of this consumption in terms of $p$, without any knowledge of the preferences.

## 12 The core

Given vectors $a, b \in \mathbb{R}^{n}$, we denote $a \geq b$ if $a_{i} \geq b_{i}$ for all coordinates $i$, we denote $a>b$ if $a \geq b$ and $a \neq b$, and denote $a \gg b$ if $a_{i}>b_{i}$ for all $i$.

In this section we will consider an exchange economy in which $X_{i}=\mathbb{R}_{L}^{+}, e_{i} \gg 0$, and $\succeq_{i}$ is closed, strictly convex and strictly monotone: if $x_{i}^{\prime}>x_{i}$ then $x_{i}^{\prime}>_{i} x_{i}$. Note that this implies that preferences are LNS.

A coalition is a subset $S$ of the consumers. A partial allocation is $\left(x_{i}^{\prime}\right)_{i \in S}$ such that each $x_{i} \in X_{i}$ and $\sum_{i \in S} x_{i}^{\prime}=\sum_{i \in S} e_{i}$.

Consider an allocation $\left(x_{i}\right)_{i}$. We say that a coalition $S$ blocks $\left(x_{i}\right)_{i}$ if there is a partial allocation $\left(x_{i}^{\prime}\right)_{i \in S}$ such that $x_{i}^{\prime}>_{i} x_{i}$ for all $i \in S$. We say that a coalition $S$ weakly blocks $\left(x_{i}\right)_{i}$ if there is a partial allocation $\left(x_{i}^{\prime}\right)_{i \in S}$ such that $x_{i}^{\prime} \geq_{i} x_{i}$ for all $i \in S$, and $x_{\ell}^{\prime}>_{\ell} x_{\ell}$ for some $\ell \in S$.

Claim 12.1. $S$ blocks $\left(x_{i}\right)_{i}$ iff it weakly blocks it.
Proof. Clearly blocking implies weak blocking. For the other direction, assume $\left(x_{i}^{\prime}\right)_{i \in S}$ witnesses that $S$ weakly blocks $\left(x_{i}\right)_{i}$, and that $x_{\ell}^{\prime}>_{\ell} x_{\ell}$. Since preferences are closed, for $\varepsilon>0$ small enough it holds that $(1-\varepsilon) x_{\ell}^{\prime}>_{\ell} x_{\ell}$.

Let $\bar{x}_{\ell}=(1-\varepsilon) x_{\ell}^{\prime}$, and for the rest of the $i \in S$ let $\bar{x}_{i}=x_{i}^{\prime}+\frac{\varepsilon}{|S|-1} x_{\ell}^{\prime}$. Then $\sum_{i \in S} \bar{x}_{i}=\sum_{i \in S} x_{i}^{\prime}$, and so $\bar{x}_{i}$ is an allocation. Furthermore, by strict monotonicity, $\bar{x}_{i}>_{i} \bar{x}_{i}$, and so $S$ blocks $\left(x_{i}\right)_{i}$.

The core of the economy is the set of allocations that are not blocked by any coalition.
Claim 12.2. Suppose $\left(x_{i}\right)_{i}$ and $p$ form an equilibrium. Then $\left(x_{i}\right)_{i}$ is in the core.
Proof. Suppose not, so that the partial allocation $\left(x_{i}^{\prime}\right)_{i \in S}$ witnesses that $S$ blocks $\left(x_{i}\right)_{i}$. Since $x_{i}^{\prime}>_{i} x_{i}$, it follows from the equilibrium condition that $p \cdot x_{i}^{\prime}>p \cdot x_{i}$. Since preferences are LNS, $p \cdot x_{i}=p \cdot e_{i}$ (Lemma 2.1) and so $p \cdot x_{i}^{\prime}>p \cdot e_{i}$. Thus

$$
\sum_{i \in S} p \cdot x_{i}^{\prime}>\sum_{i \in S} p \cdot e_{i}
$$

in contradiction to the partial allocation condition $\sum_{i \in S} x_{i}^{\prime}=\sum_{i \in S} e_{i}$.
In general, not every element of the core belongs to an equilibrium. For example, in a two consumer economy, every allocation $\left(x_{i}\right)_{i}$ that is Pareto optimal (i.e., not blocked by the coalition of both consumers) and satisfies $x_{i} \geq_{i} e_{i}$ (i.e., not blocked by a single consumer) is in the core.

The $N^{\text {th }}$ replica economy has $N \cdot I$ consumers, with each consumer of the original economy duplicated $N$ times. Each duplicate has the same endowment and preference as the original. We index consumers by ( $i, n$ ), where $i \in\{1, \ldots, I\}$ and $n \in\{1, \ldots, N\}$. Thus $e_{i, n}=e_{i}$ and $\succeq_{i, n}=\geq_{i}$.

Proposition 12.3. Let $\left(x_{i, n}\right)_{i, n}$ be in the core of the $N^{t h}$ replica economy. Then $x_{i, n}=x_{i, n^{\prime}}$ for all $i, n, n^{\prime}$.

Proof. For each $i$, fix $n(i)$ such that $x_{i, n(i)}$ is $\succeq_{i}$-minimal. For $i \in I$, let

$$
x_{i}^{\prime}=\frac{1}{N} \sum_{n=1}^{N} x_{i, n}
$$

and let $x_{i, n}^{\prime}=x_{i}^{\prime}$ for all $n \in\{1, \ldots, N\}$.
Let $S=\{(i, n(i)): i \in\{1, \ldots, I\}\}$. Suppose that $x_{\ell, n} \neq x_{\ell, n^{\prime}}$ for some $\ell, n, n^{\prime}$. Note that $x_{i, n(i)}^{\prime} \succeq_{i} x_{i, n(i)}$, with strict inequality for $i=\ell$, by strict convexity. Thus, to prove that $S$ blocks $\left(x_{i}\right)_{i}$, it remains to be shown that $\left(x_{i}^{\prime}\right)_{i \in S}$ is a partial allocation:

$$
\sum_{(i, n(i)) \in S} x_{i, n(i)}^{\prime}=\sum_{i} x_{i}^{\prime}=\sum_{i} \frac{1}{N} \sum_{n} x_{i, n}=\frac{1}{N} \sum_{i} \sum_{n} x_{i, n}=\frac{1}{N} \sum_{i, n} e_{i}=\sum_{i} e_{i}=\sum_{(i, n(i)) \in S} e_{i} .
$$

Given Proposition 12.3, we can identify every element of the core of the replica economy with an allocation of the original economy. Indeed, this allocation will be in the core of the original economy. More generally, the core of the $N^{\text {th }}$ replica economy will contain the core of the $N+1^{\text {th }}$ replica economy.

Theorem 12.4 (Debreu-Scarf). Suppose that $\left(x_{i}\right)_{i}$ is in the core of the $N^{\text {th }}$ replica economy for all $N$. Then there exists a price vector $p$ such that $\left(x_{i}\right)_{i}$ and $p$ form a Walrasian equilibrium.

Proof. Let $\left(x_{i}\right)_{i}$ be in the core of the $N^{\text {th }}$ replica economy for all $N$. Let $P_{i}=\left\{\bar{x}_{i}-e_{i}: \bar{x}_{i}>_{i} x_{i}\right\}$. Let $P$ be the convex hull of $\cup_{i} P_{i}$. Since each $P_{i}$ is convex, $P$ is the set of all $z$ such that there exist $\alpha_{i} \geq 0, \sum_{i} \alpha_{i}=1$ and $\bar{x}_{i}-e_{i} \in P_{i}$ with $z=\sum_{i} \alpha_{i}\left(\bar{x}_{i}-e_{i}\right)$. Since $P$ is open $\cup_{i} P_{i}$ is open, and $P$ is open.

We show below that $P$ does not contain 0 . Then, by the Separating Hyperplane Theorem there is some nonzero price vector $p \in \mathbb{R}^{L}$ such that $p z>0$ for all $z \in P$. We claim that $\left(x_{i}\right)_{i}$ and $p$ form an equilibrium. Since $\left(x_{i}\right)_{i}$ is an allocation, we only need to show that $x_{i} \in X_{i}^{*}\left(p, p \cdot e_{i}\right)$ for all $i$.

Suppse $\bar{x}_{i}>_{i} x_{i}$. Then $\bar{x}_{i}-e_{i} \in P_{i}$, and so $\bar{x}_{i}-e_{i} \in P$. Hence $p\left(\bar{x}_{i}-e_{i}\right)>0$, and $p \bar{x}_{i}>p e_{i}$. Thus any bundle that is better than $x_{i}$ is not affordable. We next show that $x_{i}$ is affordable: $p x_{i}=p e_{i}$. By LNS, continuity and strict monotonicity we can find a sequence $\left(x_{i}^{m}\right)_{m}$ such that $x_{i}^{m}>_{i} x_{i}$ and $\lim _{m} x_{i}^{m}=x_{i}$. Then $p x_{i}^{m}>p e_{i}$, and so $p x_{i} \geq p e_{i}$. But $\left(x_{i}\right)_{i}$ is an allocation, and so $p \sum_{i} x_{i}=p \sum_{i} e_{i}$. Thus $p x_{i}=e_{i}$. This proves that $x_{i} \in X_{i}^{*}\left(p, p \cdot e_{i}\right)$, and so we have shown that $\left(x_{i}\right)_{i}$ and $p$ form an equilibrium.

It remains to be shown that $P$ does not contain 0 . Suppose it does. Then, since $P$ is open, it also contains some $z \in \mathbb{R}_{-}^{L}$. Hence there are $\bar{x}_{i}-e_{i} \in P_{i}$ and $\alpha_{i}$ such that $z \in \mathbb{R}_{-}^{L}$ is equal to the convex combination $\sum_{i} \alpha_{i}\left(\bar{x}_{i}-e_{i}\right)$. Since each $P_{i}$ is open, we can further assume that each $\alpha_{i}$ is rational, so that $\alpha_{i}=k_{i} / N$ for some $k_{i}$ and common denominator $N$. Note that $\sum_{i} k_{i}=N$.

Consider the $N^{\text {th }}$ replica economy, and a coalition $S$ of size $N$ that consists of $k_{i}$ consumers of each type $i$. For $(i, n) \in S$, let $x_{i, n}^{\prime}=\bar{x}_{i}-z$. Since $z \in \mathbb{R}_{-}^{L}$, by monotonicity we have
that $x_{i, n}^{\prime}>_{i} \bar{x}_{i}$. Since $\bar{x}_{i}-e_{i} \in P_{i}, \bar{x}_{i}>_{i} x_{i}$, and so $x_{i, n}^{\prime}>_{i} x_{i}$. To show that $S$ blocks $\left(x_{i}\right)_{i}$, it remains to be shown that $\left(x_{i, n}^{\prime}\right)_{i, n}$ is a partial allocation:

$$
\sum_{(i, n) \in S} x_{i, n}^{\prime}=\sum_{i} k_{i}\left(\bar{x}_{i}-z\right)=\sum_{i} k_{i} \bar{x}_{i}-\sum_{i} k_{i} \sum_{j} \frac{k_{j}}{N}\left(\bar{x}_{j}-e_{j}\right)=\sum_{i} k_{i} \bar{x}_{i}-\sum_{j} k_{j}\left(\bar{x}_{j}-e_{j}\right)=\sum_{(j, n) \in S} e_{j, n} .
$$

We thus conclude that $0 \notin P$.

## 13 The core via approximate equilibria

Consider an exchange economy, an allocation $\left(x_{i}\right)_{i}$ and a price vector $p$. To quantify how far $\left(x_{i}\right)_{i}$ and $p$ are from forming an equilibrium, we consider two quantities. First, we denote by $\eta_{i}$ the amount by which $i$ exceeds her budget:

$$
\eta_{i}=\max \left\{p \cdot\left(x_{i}-e_{i}\right), 0\right\},
$$

and by $\eta=\frac{1}{I} \sum_{i} \eta_{i}$ the average amount by which the consumers exceed their budgets. Note that $\eta=0$ if and only if each consumer satisfies her budget contraint.

In equilibrium, it is impossible that a consumer chooses $x_{i}$, but strictly prefers some affordable $x_{i}^{\prime}$ to $x_{i}$. We denote by $\zeta_{i}$ the amount of money that $i$ could waste while improving her consumption:

$$
\zeta_{i}=\sup _{x_{i}^{\prime}>i x_{i}} \max \left\{p \cdot\left(e_{i}-x_{i}^{\prime}\right), 0\right\},
$$

and by $\zeta=\frac{1}{I} \zeta_{i}$ the average of these amounts.
Note that an allocation $\left(x_{i}\right)_{i}$ is a quasi-equilibrium if and only if $\eta_{i}=0$ and $\zeta_{i}=0$. Thus $\eta_{i}$ and $\zeta_{i}$ quantify the extent by which consumer $i$ violates the quasi-equilibrium conditions.

Theorem 13.1. Consider an exchange economy with $X_{i}=\mathbb{R}_{+}^{L}$, strictly monotone preferences, and $\sum_{i} e_{i} \gg 0$. Denote

$$
M=L \cdot \max _{i, \ell} e_{i, \ell}
$$

For every $\left(x_{i}\right)_{i}$ in the core there exists a $p \in \Delta_{L}$ such that $\eta \leq \frac{M}{I}$ and $\zeta \leq \frac{M}{I}$.
To prove this theorem, let $\left(x_{i}\right)_{i}$ be in the core. Let

$$
B_{i}=\left\{x_{i}^{\prime}-e_{i}: x_{i}^{\prime}>_{i} x_{i}\right\} \cup\{0\},
$$

and let $B=\sum_{i} B_{i}$.
Lemma 13.2. $B \cap \mathbb{R}_{-}^{L}=\{0\}$.
Proof. Fix $b=\sum_{i} b_{i} \in B$, with $b_{i} \in B_{i}$. Let $S$ denote those consumers for which $b_{i} \neq 0$. For the rest $b_{i}=0$, and so $b=\sum_{i \in S} b_{i}$. By the definition of $B_{i}, b=\sum_{i \in S} x_{i}^{\prime}-e_{i}$, for some $x_{i}^{\prime}>_{i} x_{i}$.

Since $x$ is in the core, $S$ cannot be a blocking coalition, and thus either $S$ is empty, or else $\left(x_{i}^{\prime}\right)_{i \in S}$ is not a partial allocation. In the former case $b=0$, and we are done. In the latter case, $b \neq 0$. Suppose towards a contradiction that $b \in \mathbb{R}_{-}^{L}$. Let $x_{k}^{\prime \prime}=x_{k}^{\prime}-b$ for some $k \in S$, for for all other $i \in S$ let $x_{i}^{\prime \prime}=x_{i}^{\prime}$. Then $\sum_{i \in S} x_{i}^{\prime \prime}=-b+\sum_{i \in S} x_{i}^{\prime}=0$, and $\left(x_{i}^{\prime \prime}\right)_{i \in S}$ is a partial allocation. Since preferences are monotone, $x_{i}^{\prime \prime}>_{i} x_{i}$, and so $S$ is a blocking coalition, and we have reached a contradiction.

The next lemma shows that a slightly weaker statement holds for the convex hull of $B$. Denote $m=(M, M, \ldots, M) \in \mathbb{R}^{L}$.

Lemma 13.3. $\operatorname{Conv}(B+m) \cap \mathbb{R}_{-}^{L} \subseteq\{0\}$.
Proof. Fix $b=\sum_{i} b_{i} \in B$. By the Shapley-Folkman Lemma (Lemma 10.3), there is a subset of the consumers $S$, of size at least $I-L$, such that $b_{i} \in B_{i}$ for $i \in S$. For $i \notin S$, we claim that $b_{i} \geq-m / L$. This clearly holds if $b_{i}=0$. Otherwise, $b_{i}$ is the convex hull of points of the form $x_{i}^{\prime}-e_{i} \geq x_{i}^{\prime}-m / L \geq-m / L$, and thus again $b_{i} \geq-m / L$.

Recalling that there are at most $L$ many indices $i$ not in $S, \sum_{i \notin S} b_{i} \geq-m$. Thus

$$
b+m=m+\sum_{i} b_{i}=m+\sum_{i \in S} b_{i}+\sum_{i \notin S} b_{i} \geq m+\sum_{i \in S} b_{i}-m=\sum_{i \in S} b_{i} .
$$

By Lemma 13.2, $\sum_{i \in S} b_{i}=0$ if it is in $R_{-}^{L}$, and so we have proved the claim.
We now apply the separating hyperplane theorem, which guarantees the existence of a $p \neq 0 \in \mathbb{R}^{L}$ such that $p \cdot z \leq 0$ for $z \in \mathbb{R}_{-}^{L}$, and $p \cdot z \geq 0$ for $z \in \operatorname{Conv}(B+m)$. From the former condition it follows that $p \geq 0$, and so, by rescaling, we can assume that $p \in \Delta_{L}$. It thus follows from the latter condition that for each $b \in B$

$$
p \cdot b \geq-p \cdot m=-M
$$

Let $\bar{B}_{i}$ denote the closure of $B_{i}$, and note that $x_{i}-e_{i} \in \bar{B}_{i}$, since by the monotonicity of the preferences $x_{i}+(\varepsilon, \ldots, \varepsilon)>_{i} x_{i}$. Let $\bar{B}=\sum_{i} \bar{B}_{i}$. Clearly, $p \cdot z \geq 0$ for $z \in \operatorname{Conv}(\bar{B}+m)$, and in particular

$$
p \cdot b \geq-M
$$

for every $b \in \bar{B}$.
Denote by $S$ the set of consumers that underspend, i.e., those $i$ for which $p \cdot\left(x_{i}-e_{i}\right)<0$. Then $\sum_{i \in S} x_{i}-e_{i} \in \bar{B}$ (as 0 is in each $B_{i}$ ), and so

$$
\sum_{i \in S} p \cdot\left(x_{i}-e_{i}\right) \geq-M
$$

I.e., the total amount underspent by those who underspend is at most $M$. Recalling that $\left(x_{i}\right)_{i}$ is an allocation, $\sum_{i} x_{i}-e_{i}=0$, and so on average consumers do not overspend: $\sum_{i} p \cdot\left(x_{i}-e_{i}\right)=$ 0 . Thus the total amount overspent by those who overspend is at most $M$ :

$$
\sum_{i} \max \left\{p \cdot\left(x_{i}-e_{i}\right), 0\right\} \leq M .
$$

Dividing both sides by $I$ yields $\eta \leq \frac{M}{I}$.
It remains to be shown that $\zeta \leq \frac{M}{I}$. Let $T$ be the set of consumers for whom $\sup _{x_{i}^{\prime}>i x_{i}} p$. $\left(e_{i}-x_{i}^{\prime}\right) \geq 0$. Note that

$$
\zeta=\frac{1}{I} \sum_{i} \sup _{x_{i}^{\prime}>i x_{i}} \max \left\{p \cdot\left(e_{i}-x_{i}^{\prime}\right), 0\right\}=\frac{1}{I} \sum_{i \in T} \sup _{x_{i}^{\prime}>i x_{i}} p \cdot\left(e_{i}-x_{i}^{\prime}\right) .
$$

Since $p \cdot b \geq-M$ for every $b \in B$, we have that if $x_{i}^{\prime}>_{i} x_{i}$ for each $i \in T$, then

$$
\frac{1}{I} p \cdot \sum_{i \in T}\left(x_{i}^{\prime}-e_{i}\right) \geq-\frac{M}{I}
$$

and

$$
\frac{1}{I} \sum_{i \in T} p \cdot\left(e_{i}-x_{i}^{\prime}\right) \leq \frac{M}{I} .
$$

Hence

$$
\zeta=\frac{1}{I} \sum_{i \in T} \sup _{x_{i}^{\prime}>i x_{i}} p \cdot\left(e_{i}-x_{i}^{\prime}\right) \leq \frac{M}{I} .
$$

## 14 Partial equilibrium: consumers

Consider an private ownership economy with two commodities: commodity 1 and 2 , where 2 shall be referred to as "money", or the "numeraire". We will denote a consumption bundle of agent $i$ by a pair $\left(x_{i}, m_{i}\right)$, where $x_{i}$ is the consumption of good 1 and $m_{i}$ is the consumption of money. We assume that agents have quasilinear utilities, so that the preference of agent $i$ is represented by

$$
u_{i}\left(x_{i}, m_{i}\right)=u_{i}\left(x_{i}\right)+m_{i},
$$

and furthermore that $u_{i}\left(x_{i}\right) \in C^{2}$ is strictly concave and strictly increasing, and that $u_{i}(0)=$ 0 . We can think here of $u_{i}\left(x_{i}\right)$ as the utility for consuming $x_{i}$ of commodity 1 , measured in units of money. And we can think of commodity 2 as capturing in it the consumption of everything that is not commodity 1 . This is a useful approach, since we often do not want to (or cannot) model the entire economy, but only a part of it.

The consumption set is $X_{i}=\mathbb{R}_{+} \times \mathbb{R}$, so that commodity 1 can only be consumed in positive amounts, but money can be consumed in both negative or positive amounts. The latter is an important assumption. We normalize the price of money to 1 , so that prices can be specified by a single number $p \in \mathbb{R}$, the price of the first commodity.

Consider the consumer's problem. Given price $p$ and wealth $w_{i}$, she will choose to consume ( $x_{i}^{*}, m_{i}^{*}$ ) if the numbers maximize $u_{i}\left(x_{i}^{*}\right)+m_{i}^{*}$ subject to the constraint $p x_{i}^{*}+m_{i} \leq w_{i}$. We solve this problem in two steps. First given a choice of $x_{i}^{*}$, the unique optimal choice of $m_{i}^{*}$ is clearly $m_{i}^{*}=w_{i}-p \cdot x_{i}^{*}$. Hence

$$
x_{i}^{*} \in \underset{x}{\operatorname{argmax}} u_{i}\left(x_{i}\right)+w_{i}-p \cdot x_{i} .
$$

The solution to this problem is independent of $w_{i}$. Indeed, an important property of quasilinear utilities is that they are invariant to changes is wealth. Thus

$$
x_{i}^{*} \in \underset{x}{\operatorname{argmax}} u_{i}\left(x_{i}\right)-p \cdot x_{i} .
$$

We can thus write $x_{i}^{*}\left(p, w_{i}\right)=x_{i}^{*}(p)$. The demand for money is

$$
m_{i}^{*}\left(p, w_{i}\right)=w_{i}-p \cdot x_{i}^{*}(p) .
$$

By our assumption that $u_{i}$ is strictly increasing and in $C^{2}$, if $x_{i}^{*}=0$ then $u_{i}^{\prime}\left(x_{i}^{*}\right) \leq p$, and the same holds with equality if if $x_{i}^{*}>0$. In this case we have that $u_{i}^{\prime}\left(x_{i}^{*}(p)\right)=p$. I.e., $x_{i}^{*}(p)$ is the inverse of the $u_{i}^{\prime}$ since $u_{i}$ is strictly concave, there is a unique solution. Thus, unless prices are too high and the agent prefers not to consume at all, the demand for commodity 1 is chosen so that the marginal utility of the commodity matches the price.

The indirect utility of consumer $i$ for price $p$ and wealth $w_{i}$ is

$$
\begin{aligned}
v_{i}\left(p, w_{i}\right) & =u_{i}\left(x_{i}^{*}(p)\right)+m_{i}^{*}\left(p, w_{i}\right) \\
& =u_{i}\left(x_{i}^{*}(p)\right)+w_{i}-p \cdot x_{i}^{*}(p) \\
& =w_{i}+u_{i}\left(x_{i}^{*}(p)\right)-p \cdot x_{i}^{*}(p)
\end{aligned}
$$

The term

$$
C S_{i}(p)=u_{i}\left(x_{i}^{*}(p)\right)-p \cdot x_{i}^{*}(p)
$$

is called the consumer surplus.
For $p$ such that $x_{i}^{*}(p)>0$, we know that $x_{i}^{*}(p)$ is the inverse of $u_{i}^{\prime}\left(x_{i}\right)$. Hence, and because $u_{i}^{\prime}$ is bounded, for $p$ large enough $x_{i}^{*}(p)=0$. Denote $\bar{p} \in \mathbb{R} \cup\{\infty\}$ the lowest $p$ such that $x_{i}^{*}(p)=0$.

Recall that if $F \in C^{2}$ is strictly increasing and $f$ is its derivative, then

$$
\int_{1}^{b} f^{-1}(y) \mathrm{d} y=\left[y f^{-1}(y)-F\left(f^{-1}(y)\right)\right]_{a}^{b}
$$

Thus

$$
\int_{p}^{\bar{p}} x_{i}^{*}(q) \mathrm{d} q=\left[q x_{i}^{*}(q)-u_{i}\left(x_{i}^{*}(q)\right)\right]_{p}^{\bar{p}}=u_{i}\left(x_{i}^{*}(p)\right)-p x_{i}^{*}(p)=C S_{i}(p)
$$

In case $\bar{p}=\infty$ to show that the second equality holds we need to show that $\lim _{q \rightarrow \infty} q x_{i}^{*}(q)=0$. This is left as an exercise.

Note also that

$$
C S_{i}=\int_{0}^{x_{i}^{*}(p)}\left[u_{i}^{\prime}(x)-p\right] \mathrm{d} x .
$$

The integrand $u_{i}^{\prime}(x)-p$ is the marginal benefit to the consumer for consuming at level $x$, where she gains marginal utility $u_{i}^{\prime}(p)$ and pays marginal cost $p$. This integrand is positive at all $x<x_{i}^{*}(p)$ since $u_{i}^{\prime}(x)<p$ in that region.

Let $x^{*}(p)=\sum_{i} x_{i}^{*}(p)$. If we let $u^{\prime}$ be the inverse of $x$, and $u$ the integral of $u^{\prime}$, then $u$ is a utility function that induces demand $x^{*}(p)$. We thus always have a representative consumer. A simple calculation shows that the consumer surplus for this representative consumer is equal to the sums of the surpluses of the individual consumers.

## 15 Partial equilibrium: production

Suppose that it costs $c_{i}(y)$ for producer $i$ to produce $y$ units of commodity 1. This corresponds to a firm whose production set is $Y=\left\{(y,-m): y \in \mathbb{R}_{+}, m \in \mathbb{R}_{+}, m \geq c_{i}(y)\right\}$. We will assume that $c_{i}: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$is in $C^{2}$, strictly increasing and strictly convex. Note that (strict) convexity of $Y$ corresponds to (strict) convexity of $c$.

At price $p$, firm $i$ will choose to produce $y_{i}^{*}(p)$ units of commodity 1 , which will cost it $-c_{i}(y)$ money. The firm's problem is hence solved by

$$
y_{i}^{*}(p) \in \underset{y \in Y}{\operatorname{argmax}} p \cdot y-c_{i}(y)
$$

If $y_{i}^{*}=0$ then $c^{\prime}\left(y^{*}\right) \geq p$. If $y_{i}^{*}>0$ then it must be that $c_{i}^{\prime}\left(y^{*}(p)\right)=p$, and thus $y_{i}^{*}(p)$ is the inverse of $c_{i}^{\prime}(y)$.

We can let $Y=\sum_{i} Y_{i}$ and $y^{*}(p)=\sum_{i} y_{i}^{*}(p)$. By our assumptions, $y^{*}(p)$ is strictly increasing. Let $c(y)=\min \{m:(y,-m) \in Y\}$. The set $Y$ is strictly convex, since it is the sum of strictly convex sets. Hence $c(y)$ is strictly convex.

## 16 Partial equilibrium conditions

We will assume that consumers are endowed with money only. We will consider equilibria in which $x_{i}>0$ for all $i$. Thus, an allocation $\left(\left(x_{i}, m_{i}\right)_{i},\left(y_{i}\right)_{i}\right)$ and a price vector $p$ such that $x_{i}>0$ are an equilibrium if $u_{i}^{\prime}\left(x_{i}\right)=p, c_{i}^{\prime}\left(y_{i}\right)=p, \sum_{i} x_{i}=\sum_{i} y_{i}$ and $\sum_{i} m_{i}=\sum_{i} e_{i}$. Note that it must be that $p>0$, since otherwise the consumers will consume an infinite amount.

The next claim shows that we can dispense with the last condition.
Claim 16.1. In a general private ownership economy with LNS preferences, an allocation $\left(\left(x_{i}\right)_{i},\left(y_{i}\right)_{i}\right)$ and a price vector $p$ with $p_{L} \neq 0$ are an equilibrium if $x_{i} \in X_{i}^{*}\left(p, w_{i}\right), y_{j} \in Y_{j}^{*}(p)$, and $\sum_{i} x_{i, \ell}=\sum_{j} y_{j, \ell}$ for $\ell \in\{1, \ldots, L-1\}$.
Proof. Since preferences are LNS, by Lemma $2.1 p \cdot x_{i}=w_{i}$. Summing over $i$ yields

$$
p \cdot \sum_{i} x_{i}-w_{i}=0
$$

Writing this expression commodity by commodity and separating the last commodity yields

$$
p_{L} \cdot \sum_{i}\left(x_{i, L}-w_{i, L}\right)=-\sum_{\ell \neq L} p_{\ell} \cdot \sum_{i}\left(x_{i, \ell}-w_{i, \ell}\right) .
$$

Substituting $w_{i}=\sum_{j} \theta_{i j} p \cdot y_{j}$ yields

$$
p_{L} \cdot \sum_{i}\left(x_{i, L}-\sum_{j} \theta_{i j} p \cdot y_{j, L}\right)=-\sum_{\ell \neq L} p_{\ell} \cdot \sum_{i}\left(x_{i, \ell}-\sum_{j} \theta_{i j} p \cdot y_{j, \ell}\right) .
$$

Changing the order of summation and using $\sum_{i} \theta_{i j}=1$ we get

$$
p_{L} \cdot\left(\sum_{i} x_{i, L}-\sum_{j} y_{j, L}\right)=-\sum_{\ell \neq L} p_{\ell} \cdot\left(\sum_{i} x_{i, \ell}-\sum_{j} y_{j, \ell}\right)=0
$$

and so, since $p_{L} \neq 0$,

$$
\sum_{i} x_{i, L}-\sum_{j} y_{j, L}=0
$$

and all the equilibrium conditions are satisfied.
We now turn to a comparative statics example, which is taken from [1]. Suppose that a sales tax is imposed, and consumers have to pay $t>0$ money for each unit of commodity 1 that they consume. We thus have a family of economies indexed by $t$, where production costs and endowments are not dependent on $t$, but consumer preferences are represented by

$$
u_{i}(x, m)=u_{i}(x)-t x+m .
$$

Following the analysis above, in equilibrium,

$$
\begin{equation*}
u_{i}^{\prime}\left(x_{i}\right)=p+t \quad \text { and } \quad c_{i}^{\prime}\left(y_{i}\right)=p . \tag{16.1}
\end{equation*}
$$

How do equilibrium prices, consumption and production change when we change the tax? Denote $x=\sum_{i} x_{i}$ and $y=\sum_{j} y_{j}$ the total consumption and production in equilibrium, and by $u$ and $c$ the corresponding aggregate utility and cost functions. We assume both are differentiable. Since consumption depends only on the price and tax, we denote by $x(p, t)$ consumer demand given price $p$ and tax $t$. By (16.1) $x$ depends on $p$ and $t$ only through $p+t$, and thus we can write $x$ as a function of a single variable $x(p+t)=x(p, t)$.

Production does not depend on taxation, and so we denote by $y(p)$ production at price $p$. We denote by $p(t)$ the equilibrium price when taxes are set to $t$. In equilibrium we know that

$$
x(p(t)+t)=y(p(t)) .
$$

Differentiating this equation with respect to $t$ yields

$$
\left(p^{\prime}(t)+1\right) x^{\prime}(p(t)+t)=p^{\prime}(t) y^{\prime}(p(t)),
$$

Rearranging, we get

$$
-p^{\prime}(t)=\frac{-x^{\prime}(p(t)+t)}{y^{\prime}(p(t))-x^{\prime}(p(t)+t)} .
$$

We know that $x^{\prime}$ is negative and $y^{\prime}$ is positive. It thus follows that $0 \leq-p^{\prime}(t) \leq 1$. That is, when we increase taxes by a cent, prices will decrease by something that is between 0 and a cent. Since consumers also pay the tax, their effective price $p(t)+t$ increases.

When $y^{\prime}(p(t))$ is very big as compared to $-x^{\prime}(p(t)+t),-p^{\prime}(t)$ will be very close to 0 , so that prices change very little in response to taxation. The effective price for consumers will, however, increase almost linearly with the taxation. When $y^{\prime}(p(t))$ is very small, $-p^{\prime}(t)$ will be almost 1 . In this case the effective price to consumers will not change by much. These two cases are referred to as high pass-through and low pass-through, respectively.

## 17 Uncertainty

In this section we explore how our setting of a private ownership economy can incorporate uncertainty. We will consider $L_{p}$ physical commodities, and $S$ states of nature. The set of commodities will have size $L=L_{p} \times S$. Commodities will be denoted as a pair $(\ell, s)$. The interpretation is that exactly one of the states realizes, and what is traded is a physical commodity whose delivery is contingent on that state. Thus, if consumer $i$ consumes an amount $x_{i,(\ell, s)}$ of commodity $(\ell, s)$, that is taken to mean that contingent on the state realization $s$, she will get that amount of the physical commodity $\ell$. Our notion of an equilibrium is unchanged, so that consumers have preferences over bundles of commodities, and an equilibrium consists of an allocation that clears the market, firms that maximize profit, and agents who consume an optimal bundle given their budget. In this setting an equilibrium is called an Arrow-Debreu equilibrium.

As an example, consider an exchange economy with two agents, a single physical commodity and two states. Let the preference of consumer $i$ be given by

$$
u_{i}\left(x_{i, s_{1}}, x_{i, s_{2}}\right)=\pi_{i} v_{i}\left(x_{i, s_{1}}\right)+\left(1-\pi_{i}\right) v_{i}\left(x_{i, s_{2}}\right),
$$

for some strictly concave, differentiable $v_{i}: \mathbb{R} \rightarrow \mathbb{R}$ and $\pi_{i} \in[0,1]$. An interpretation of this preference is that the consumer is an expected utility maximizer, and has prior belief $\pi_{i}$ that the state is $s_{1}$, and utility $v_{i}$ for the physical good. Suppose that $e_{1}=(1,0)$ and $e_{2}=(0,1)$. Thus, in state $s_{1}$ consumer 1 is endowed with one unit of the physical product, and in state $s_{2}$ consumer 2 is endowed with one unit of the physical product.

Suppose ( $x_{1}, x_{2}$ ) and $p$ form an interior equilibrium. Then

$$
\frac{p_{1}}{p_{2}}=\frac{\pi_{1} v_{1}^{\prime}\left(x_{1, s_{1}}\right)}{\left(1-\pi_{1}\right) v_{1}^{\prime}\left(x_{1, s_{2}}\right)}=\frac{\pi_{2} v_{2}^{\prime}\left(x_{2, s_{1}}\right)}{\left(1-\pi_{2}\right) v_{1}^{\prime}\left(x_{2, s_{2}}\right)}=\frac{\pi_{2} v_{2}^{\prime}\left(1-x_{1, s_{1}}\right)}{\left(1-\pi_{2}\right) v_{2}^{\prime}\left(1-x_{1, s_{2}}\right)} .
$$

If $\pi_{1}=\pi_{2}=\pi$ then this implies that

$$
v_{1}^{\prime}\left(x_{1, s_{1}}\right) v_{2}^{\prime}\left(1-x_{1, s_{2}}\right)=v_{2}^{\prime}\left(1-x_{1, s_{1}}\right) v_{1}^{\prime}\left(x_{1, s_{2}}\right),
$$

which is possible only if $x_{1, s_{1}}=x_{1, s_{2}}$, and hence also $x_{2, s_{1}}=x_{2, s_{2}}$, by the strict concavity of $v_{1}$ and $v_{2}$. In this case, consumers demand the same amount of physical good in both states, and thus face no risk. Prices reflect beliefs: $p_{1} / p_{2}=\pi /(1-\pi)$. In the general case, if $\pi_{1}>\pi_{2}$ then $x_{1, s_{1}}>x_{1, s_{2}}$ and $x_{2, s_{1}}<x_{2, s_{2}}$.

## 18 Pari-mutuel gambling

Consider a horse race, in which $I$ gamblers each place bets on one of $L$ horses. Each gambler has a budget $m_{i}>0$ which they completely spend. We denote $\sum_{i} m_{i}=M$.

We will consider two equivalent ways of thinking about these markets. In the first, each gambler $i$ decides how much money $m_{i, \ell}$ to bet on horse $\ell$. After the race, if horse $\ell$ wins, all the money collected is distributed between those who bet on $\ell$, in proportion to the amount they bet. So that gambler $i$ receives

$$
\frac{m_{i, \ell}}{\sum_{h} m_{h, \ell}} M
$$

An equivalent description is one in which, for each horse $\ell$, each gambler may buy any amount of tickets for that horse, for some price $p_{\ell}$. We denote the number of tickets bought by gambler $i$ for horse $\ell$ by $x_{i, \ell}$, so that the amount spent on these tickets is $m_{i, \ell}=p_{\ell} x_{i, \ell}$.

After the race, given that horse $\ell$ won, each ticket sold for horse $\ell$ is worth a unit of money, and the rest are worthless. Thus, when horse $\ell$ wins, gambler $i$ 's payoff is equal to $x_{i, \ell}$. The market clearing condition is that the total amount of winnings distributed is always equal to the total amount of money collected. I.e., for any horse $\ell, \sum_{i} x_{i, \ell}=M$. Since $x_{i, \ell}=m_{i, \ell} / p_{\ell}$, it follows that

$$
\sum_{i} m_{i, \ell} / p_{\ell}=M
$$

or

$$
p_{\ell}=\frac{\sum_{i} m_{i, \ell}}{M} .
$$

That is, $p_{\ell}$ is the fraction of money gambled on horse $\ell$, of all the money gambled by all the gamblers.

We assume that the gamblers each have a prior $\pi_{i, \ell}$ that horse $\ell$ will win the race. They are risk neutral, and so aim to maximize their expected return, which for $i$ is equal to

$$
\begin{equation*}
u_{i}\left(x_{i}\right)=\sum_{\ell} \pi_{i, \ell} x_{i, \ell} . \tag{18.1}
\end{equation*}
$$

Thus, in equilibrium, gambler $i$ will maximize $u_{i}\left(x_{i}\right)$ subject to the constraint $\sum_{\ell} p_{\ell} x_{i, \ell}=m_{i}$. That is, she will gamble a positive amount on horse $\ell$ only if

$$
\ell \in \underset{k}{\operatorname{argmax}} \frac{\pi_{i, k}}{p_{k}}
$$

A pari-mutuel equilibrium for priors $\left(\pi_{i, \ell}\right)_{i, \ell}$ and budgets $\left(m_{i}\right)_{i}$ is a gambles profile $\left(x_{i, \ell}\right)_{i, \ell}$ and a price vector $p$ such that

1. For all $i$ it holds that $x_{i}$ maximizes $u_{i}(x)=\sum_{\ell} \pi_{i, \ell} x_{i, \ell}$ subject to $\sum_{\ell} p_{\ell} x_{i, \ell}=m_{i}$.
2. $\sum_{i} x_{i, \ell}=M$ for every $\ell$.

This setting is equivalent to an exchange economy in which there is a single physical commodity (money) and $L$ states (which horse won). Each consumer $i$ is endowed with $e_{i}=\left(m_{i}, m_{i}, \ldots, m_{i}\right)$ : a sure amount of money. Their preference is given by (18.1).

Theorem 18.1 (Eisenberg \& Gale). Suppose that for each $\ell$ there is an $i$ such that $\pi_{i, \ell}>0$. Then there exist $\left(x_{i, \ell}\right)_{i, \ell}$ and $p \gg 0$ that form an equilibrium.

Note that the condition that $\pi_{i, \ell}>0$ for some $i$ is almost without loss of generality, for if this does not hold then we can remove horse $\ell$ from the race and proceed with the rest. Before proving this theorem we will introduce Cobb-Douglas preferences. Consider a single consumer whose preferences over $L$ goods is represented by the utility function

$$
u\left(x_{1}, \ldots, x_{L}\right)=\prod_{\ell=1}^{L} x_{\ell}^{m_{\ell}}
$$

for some positive exponents $m_{1}, \ldots, m_{L}$. We denote $M=\sum_{\ell} M_{\ell}$. Given a price vector $p \in \mathbb{R}^{L}$ and total wealth $w$, the demand $x^{*}$ will maximize $u$ subject to $\sum_{\ell} p_{\ell} x_{\ell}^{*} \leq w$. Equivalently, we can maximize $\log u$ under this constraint. Adding a Lagrange multiplier $\lambda$ for the constraint we get that $x^{*}, \lambda$ maximize

$$
\sum_{\ell} m_{\ell} \log x_{\ell}-\lambda\left(\sum_{\ell} p_{\ell} x_{\ell}-w\right) .
$$

The first order conditions give

$$
\frac{m_{\ell}}{x_{\ell}}=\lambda p_{\ell}
$$

which we rearrange to

$$
p_{\ell} x_{\ell}=\frac{m_{\ell}}{\lambda}
$$

To meet the budget constraint we must have that $\lambda=w / M$, and the solution is hence

$$
p_{\ell} x_{\ell}=\frac{w}{M} m_{\ell}
$$

An important observation is that the total amount of money spent on good $\ell$ is proportional to the exponent $m_{\ell}$, regardless of the budget. This makes these preferences easy to work with, and, as we shall see now, makes them useful for other reasons.

To prove Theorem 18.1 we will consider the social welfare function

$$
U(x)=\prod_{i} u_{i}\left(x_{i}\right)^{m_{i}} .
$$

Denote

$$
\Phi(x)=\log U(x)=\sum_{i} m_{i} \log u_{i}\left(x_{i}\right)=\sum_{i} m_{i} \log \left(\sum_{\ell} \pi_{i, \ell} x_{i, \ell}\right) .
$$

Note that

$$
\frac{\partial \Phi}{\partial x_{i, \ell}}(x)=\frac{m_{i} \pi_{i, \ell}}{\sum_{\ell} \pi_{i, \ell} \cdot x_{i, \ell}}=\frac{m_{i} \pi_{i, \ell}}{u_{i}\left(x_{i}\right)} .
$$

Consider the problem of maximizing $U$ (or equivalently $\Phi$ ) subject to the market clearing constraints $\sum_{i} x_{i, \ell}=M$ and the feasibility constraints $x_{i, \ell} \geq 0$. Clearly an optimum $x$ exists, since $U$ is continuous on the constrained, compact domain. In this optimum $u_{i}\left(x_{i}\right)>0$ for all $i$, since otherwise $U(x)=0$, and $U$ takes values higher than zero, for example by having each agent gamble equal amounts on each horse.

If we denote by $p_{\ell}$ the Lagrange multiplier for the market clearing constraint $\sum_{i} x_{i, \ell}=M$, we get that $x$ is a maximizer if and only if it satisfies the conditions of the KKT Theorem: $\frac{\partial \Phi}{\partial x_{i, \ell}}(x)=p_{\ell}$ whenever $x_{i, \ell}>0$, in which case

$$
\begin{equation*}
p_{\ell}=\frac{m_{i} \pi_{i, \ell}}{u_{i}\left(x_{i}\right)}, \tag{18.2}
\end{equation*}
$$

and

$$
\begin{equation*}
p_{\ell} \geq \frac{m_{i} \pi_{i, \ell}}{u_{i}\left(x_{i}\right)} . \tag{18.3}
\end{equation*}
$$

when $x_{i, \ell}=0$. Note that $p_{\ell}>0$, since by assumption $\pi_{i, \ell}>0$ for some $i$.
Multiplying both sides of (18.2) by $x_{i, \ell}$ we get

$$
p_{\ell} x_{i, \ell}=\frac{m_{i} \pi_{i, \ell} x_{i, \ell}}{u_{i}\left(x_{i}\right)}
$$

which holds for all $\ell$ : when $x_{i, \ell}>0$ it holds by (18.2), and when $x_{i, \ell}=0$ both sides vanish. Summing over $\ell$ we get

$$
\sum_{\ell} p_{\ell} x_{i, \ell}=\sum_{\ell} \frac{m_{i} \pi_{i, \ell} x_{i, \ell}}{u_{i}\left(x_{i}\right)}=m_{i} \frac{\sum_{\ell} \pi_{i, \ell} x_{i, \ell}}{u_{i}\left(x_{i}\right)}=m_{i}
$$

since (18.2) is satisfied whenever $x_{i, \ell} \neq 0$. So miraculously the budget constraint is satisfied. This is in fact due to the clever choice of $\Phi$ as taking a Cobb-Douglas form. If $x_{i, \ell}=0$ then by (18.3)

$$
\frac{\pi_{i, \ell}}{p_{\ell}} \leq \frac{u_{i}(x)}{m_{i}},
$$

and this holds with equality if $x_{i, \ell}>0$. Thus $\pi_{i, \ell} / p_{\ell}$ is maximal for every $\ell$ for which $x_{i, \ell}>0$, the choice of $x_{i}$ is optimal, and $\left(x_{i, \ell}\right)_{i, \ell}$ and $p$ form an equilibrium. This completes the proof of Theorem 18.1.

While in general there is not a unique equilibrium, the prices in every equilibrium are unique. We now prove this. Suppose $\left(x_{i, \ell}^{\prime}\right)_{i, \ell}$ and $p^{\prime}$ form an equilibrium, as do $\left(x_{i, \ell}^{\prime}\right)_{i, \ell}$ and $p^{\prime}$.

Let

$$
\begin{aligned}
\mu_{i} & =\max _{\ell} \frac{\pi_{i, \ell}}{p_{\ell}} \\
\mu_{i}^{\prime} & =\max _{\ell} \frac{\pi_{i, \ell}}{p_{\ell}^{\prime}} .
\end{aligned}
$$

It follows that

$$
\begin{align*}
& \pi_{i, \ell} \leq \mu_{i} p_{\ell} \\
& \pi_{i, \ell} \leq \mu_{i}^{\prime} p_{\ell}^{\prime} \tag{18.4}
\end{align*}
$$

Under $x$, the expected revenue for gambler's $i$ investment into horse $\ell$ is $x_{i, \ell} \pi_{i, \ell}$. By the definition of $\mu, x_{i, \ell} \mu_{i} p_{\ell}=x_{i, \ell} \pi_{i, \ell}$ (when $\mu_{i} \neq \pi_{i, \ell} / p_{\ell}$ both vanish, because $x_{i, \ell}$ vanishes). Thus by (18.4)

$$
x_{i, \ell} \mu_{i} p_{\ell} \leq x_{i, \ell} \mu_{i}^{\prime} p_{\ell}^{\prime},
$$

and by a symmetric argument

$$
x_{i, k}^{\prime} \mu_{i}^{\prime} p_{k}^{\prime} \leq x_{i, k}^{\prime} \mu_{i} p_{k}
$$

Multiplying the inequalities by $x_{i, k}^{\prime} / p_{\ell}$ and $x_{i, \ell} / p_{k}^{\prime}$ respectively, we arrive at

$$
\begin{aligned}
x_{i, k}^{\prime} x_{i, \ell} \mu_{i} & \leq x_{i, k}^{\prime} x_{i, \ell} \mu_{i}^{\prime} \frac{p_{\ell}^{\prime}}{p_{\ell}} \\
x_{i, k}^{\prime} x_{i, \ell} \mu_{i}^{\prime} \frac{p_{k}^{\prime}}{p_{k}} & \leq x_{i, k}^{\prime} x_{i, \ell} \mu_{i} .
\end{aligned}
$$

Combining into one inequality yields

$$
x_{i, k}^{\prime} x_{i, \ell} \mu_{i}^{\prime} \frac{p_{k}^{\prime}}{p_{k}} \leq x_{i, k}^{\prime} x_{i, \ell} \mu_{i}^{\prime} \frac{p_{\ell}^{\prime}}{p_{\ell}} .
$$

We now multiply by $p_{k}^{\prime} p_{\ell}$, divide by $\mu_{i}^{\prime}$ and sum over $k, \ell$ :

$$
\sum_{k, \ell}\left(p_{k}^{\prime} x_{i, k}^{\prime}\right)\left(p_{\ell} x_{i, \ell}\right) \frac{p_{k}^{\prime}}{p_{k}} \leq \sum_{k, \ell}\left(p_{k}^{\prime} x_{i, k}^{\prime}\right)\left(p_{\ell} x_{i, \ell}\right) \frac{p_{\ell}^{\prime}}{p_{\ell}} .
$$

Since $\sum_{\ell} p_{\ell} x_{i, \ell}=m_{i}=\sum_{l} p_{k}^{\prime} x_{i, k}^{\prime}$ we get

$$
\sum_{k}\left(p_{k}^{\prime} x_{i, k}^{\prime}\right) \frac{p_{k}^{\prime}}{p_{k}} \leq \sum_{\ell}\left(p_{\ell} x_{i, \ell}\right) \frac{p_{\ell}^{\prime}}{p_{\ell}} .
$$

Summing over $i$ and dividing by $M$ yields

$$
\sum_{k} p_{k}^{\prime} \frac{p_{k}^{\prime}}{p_{k}} \leq \sum_{\ell} p_{\ell} \frac{p_{\ell}^{\prime}}{p_{\ell}}=1
$$

Equivalently

$$
\sum_{k}\left(\frac{p_{k}^{\prime}}{p_{k}}\right)^{2} p_{k} \leq 1
$$

i.e., the second moment (according to $p$ ) of $p_{k}^{\prime} / p_{k}$ is at most 1 . The expectation of $p_{k}^{\prime} / p_{k}$ is $\sum_{k}\left(p_{k}^{\prime} / p_{k}\right) p_{k}=1$. Since the variance of any random variable is non-negative (i.e., the second moment minus the expectation squared is non-negative) it follows that $p_{k}^{\prime} / p_{k}$ has zero variance, and thus must equal 1 for every $k$. Thus $p_{k}^{\prime}=p_{k}$.

## 19 Radner equilibria

Consider an exchange economy with $L_{p}$ physical goods and $S$ states. In an Arrow-Debreu equilibrium there are prices for each of the $L=S \cdot L_{p}$ contingent goods. We think of trade as occurring before the state has been realized, and of consumption as occurring after the state has been realized. The equilibrium conditions are
(i) $x_{i}$ maximizes $\succeq_{i}$ subject to $\sum_{s, \ell} p_{s, \ell} x_{i, s, \ell} \leq \sum_{s, \ell} p_{s, \ell} e_{i, s, \ell}$.
(ii) $\sum_{i} x_{i, s, \ell}=\sum_{i} e_{i, s, \ell}$ for each commodity $(s, \ell)$.

One could imagine that trade occurs only after the state is realized, so that the budget constraint (i) needs to hold in each state separately. This would correspond to replacing (i) by
(i') $x_{i}$ maximizes $\geq_{i}$ subject to $\sum_{\ell} p_{s, \ell} x_{i, s, \ell} \leq \sum_{\ell} p_{s, \ell} e_{i, s, \ell}$ for each state $s$.
Here, for each state $s$ we think of each price vector $p_{s,} \in \mathbb{R}^{L_{p}}$ as the vector of spot prices for a market that opens once state $s$ is realized. Note that if $x_{i}$ satisfies (i) and (ii) then it is Pareto optimal, by the first welfare theorem. Hence there is, in a sense, no reason for further trades after the state has been revealed when all contingent goods are traded before the state is revealed. But if instead it satisfies (i') and (ii) then it may not be Pareto optimal. For example, in a market described in $\S 17$ (a single physical good, two states, $e_{1}=(1,0)$ and $e_{2}=(0,1)$, and expected utility maximizing consumers) it is no longer possible for the consumers to insure each other, and each must consume only in one of the states, since she has zero wealth in the other.

As we now explain, we can still achieve Pareto optimality while trading after the state is revealed, by allowing trade in just one physical good (which we can think of as money, even though we will not assume quasi-linear utilities) before the state is realized.

In a Radner equilibrium we consider an exchange economy with $L_{p}$ physical goods and $S$ states. We will assume that $X_{i}=\mathbb{R}_{+}^{L}$ and preferences are strictly monotone, and $\sum_{i} e_{i} \gg 0$. We imagine that trade takes place in two stages.

In $t=0$ the consumers trade contingent quantities of good 1 only, at some contingent price vector $q \in \mathbb{R}^{S}$. We denote by $z_{i, s}$ the amount of good 1 at state $s$ that consumer $i$ buys. Thus consumer $i$ spends $\sum_{s} q_{s} z_{i, s}$ at $t=0$. As none of the endowment is consumed at this stage, the consumers all have a budget of zero for this trade, and so $\sum_{s} q_{s} z_{i, s} \leq 0$. The market clearing condition is $\sum_{s} z_{i, s}=0$.

In $t=1$ the state is realized, and a spot market opens at the realized state $s$. The wealth of consumer $i$ includes the value of her endowment, plus the value of the contingent goods purchased before: $\sum_{\ell} p_{s, \ell} e_{i, \ell}+p_{s, 1} z_{i, s}$.

Thus, $\left(z_{i, s}\right)_{i, s},\left(x_{i, s, \ell}\right)_{i, s, \ell},\left(p_{s, \ell}\right)_{s, \ell}$ and $\left(q_{s}\right)_{s}$, form a Radner equilibrium if
(i) $x_{i}$ and $z_{i}$ maximize $\succeq_{i}$ subject to $\sum_{s} q_{s} z_{i, s} \leq 0$ and $\sum_{\ell} p_{s, \ell} x_{i, s, \ell} \leq \sum_{\ell} p_{s, \ell} e_{i, s, \ell}+p_{s, 1} z_{i, s}$ for each state $s$.
(ii) $\sum_{i} z_{i, s}=0$ for each state $s$.
(iii) $\sum_{i} x_{i, s, \ell}=\sum_{i} e_{i, s, \ell}$ for each commodity ( $s, \ell$ ).

Note that when trading at $t=0$, consumers are (correctly) anticipating the prices at $t=1$, basing their choice of $z_{i}$ on them. The next claim shows that we can assume without loss of generality that $q_{s}=p_{s, 1}$, so that the price of good 1 does not change from $t=0$ to $t=1$.

Claim 19.1. Suppose $\left(z_{i, s}\right)_{i, s},\left(x_{i, s, \ell}\right)_{i, s, \ell},\left(p_{s, \ell}\right)_{s, \ell}$ and $\left(q_{s}\right)_{s}$ form a Radner equilibrium, with $p_{s, 1}>0$. Let $p_{s, \ell}^{\prime}=\frac{q_{s}}{p_{s, 1}} p_{s, \ell}$ (so that $q_{s}=p_{s, 1}^{\prime}$ ). Then $\left(z_{i, s}\right)_{i, s},\left(x_{i, s, \ell}\right)_{i, s, \ell},\left(p_{s, \ell}^{\prime}\right)_{s, \ell}$ and $\left(q_{s}\right)_{s}$ form a Radner equilibrium.

Proof. It suffices to check that $x_{i}$ and $z_{i}$ maximize $\geq_{i}$ subject to $\sum_{\ell} p_{s, \ell}^{\prime}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq p_{s, 1}^{\prime} z_{i, s}^{\prime}$ and $\sum_{s} q_{s} z_{i, s} \leq 0$ for each state $s$ for each state $s$.

This indeed holds, since the condition

$$
\sum_{\ell} p_{s, \ell}^{\prime}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq p_{s, 1}^{\prime} z_{i, s}
$$

is equivalent to

$$
\sum_{\ell} \frac{q_{s}}{p_{s, 1}} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq \frac{q_{s}}{p_{s, 1}} p_{s, 1} z_{i, s}
$$

which is equivalent to

$$
\sum_{\ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq p_{s, 1} z_{i, s}
$$

Note that since $\sum_{i} e_{i} \gg 0$, since preferences are strictly monotone, prices must be positive, since otherwise maximal demands would not exist. We will therefore describe Radner equilibria by just specifying $z, x$ and $p$, with the implied assumption that $q_{s}=p_{s, 1}$.

Proposition 19.2. 1. Suppose $\left(z_{i, s}\right)_{i, s},\left(x_{i, s, \ell}\right)_{i, s, \ell}$ and $\left(p_{s, \ell}\right)_{s, \ell}$ form a Radner equilibrium. Then $\left(x_{i, s, \ell}\right)_{i, s, \ell}$ and $\left(p_{s, \ell}\right)_{s, \ell}$ form an Arrow-Debreu equilibrium.
2. Suppose $\left(x_{i, s, \ell}\right)_{i, s, \ell}$, and $\left(p_{s, \ell}\right)_{s, \ell}$ form an Arrow-Debreu equilibrium. Then there are $\left(z_{i, s}\right)_{i, s}$ such that $\left(z_{i, s}\right)_{i, s},\left(x_{i, s, \ell}\right)_{i, s, \ell}$ and $\left(p_{s, \ell}\right)_{s, \ell}$ form a Radner equilibrium.

Proof. In the Arrow-Debreu setting, consumer $i$ chooses $x_{i}$ as a maximal element from

$$
A_{i}=\left\{\left(x_{i, s, \ell}\right)_{s, \ell}: \sum_{s, \ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq 0\right\}
$$

We can reformulate the consumer's problem in the the Radner setting to maximize $x_{i}$ over the set

$$
R_{i}=\left\{\left(x_{i, s, \ell}\right)_{s, \ell}: \exists\left(z_{i, s}\right)_{s} \text { s.t. } \sum_{s} p_{s, 1} z_{i, s} \leq 0 \text { and } \sum_{\ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq p_{s, 1} z_{i, s} \text { for all } s\right\}
$$

We show that $A_{i}=R_{i}$. Fix $x_{i} \in A_{i}$. Let

$$
\begin{equation*}
z_{i, s}=\frac{1}{p_{s, 1}} \sum_{\ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) . \tag{19.1}
\end{equation*}
$$

Then it is immediate that $\sum_{s} p_{s, 1} z_{i, s} \leq 0$ and $\sum_{\ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq p_{s, 1} z_{i, s}$ (the latter with equality), and so $x_{i} \in R_{i}$.

Conversely, fix $x_{i} \in R_{i}$. Then summing the second inequality in the definition of $R_{i}$ over $s$ yields

$$
\sum_{s, \ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right) \leq \sum_{s} p_{s, 1} z_{i, s}
$$

which is at most 0 by the first inequality in the definition of $R_{i}$. Thus $x_{i} \in A_{i}$.

1. Since $R_{i}=A_{i}, x_{i}$ is a maximal element of $A_{i}$. Since it is also an allocation, we have an Arrow-Debreu equilibrium.
2. Since $R_{i}=A_{i}, x_{i}$ is a maximal element of $R_{i}$, and furthermore, as the proof above shows, if we choose $z_{i}$ by (19.1), $x_{i}$ and $z_{i}$ will solve the consumer's problem. Since $x_{i}$ is an allocation, it remains to be shown that $\sum_{i} z_{i, s}=0$ for all $s$. By our choice of $z_{i, s}$,

$$
\sum_{i} z_{i, s}=\sum_{i} \frac{1}{p_{s, 1}} \sum_{\ell} p_{s, \ell}\left(x_{i, s, \ell}-e_{i, s, \ell}\right)=\frac{1}{p_{s, 1}} \sum_{\ell} p_{s, \ell} \sum_{i}\left(x_{i, s, \ell}-e_{i, s, \ell}\right)
$$

Since $\left(x_{i, s, \ell}\right)_{i}$ is an allocation, $\sum_{i}\left(x_{i, s, \ell}-e_{i, s, \ell}\right)=0$, and so $\sum_{i} z_{i, s}=0$.

## 20 Asset pricing

We will now consider an economy with a single physical commodity (potatoes) and a finite set of $S$ states. Consumers have strictly monotone preferences over the $S$ contingent commodities. Each consumer is endowed with some $e \in \mathbb{R}_{+}^{S}$. An asset $a \in \mathbb{R}^{S}$ is a contract that delivers $a_{s}$ potatoes in state $s$. We will think of assets as column vectors.

Some examples of assets include the risk free asset $a_{s}=1$. Another is the for state $s^{\prime}$, given by $a_{s}=1_{s=s^{\prime}}$. Given an asset $a$, an asset $b$ is a call option for $a$ with strike price $p$ if $b_{s}=\left(a_{s}-p\right)^{+}$. The asset $c$ is a put option with strike price $p$ if $c_{s}=\left(p-a_{s}\right)^{+}$.

A market will consist of $J$ assets $a^{1}, \ldots, a^{J}$, and an asset price vector $q \in \mathbb{R}_{+}^{J}$, which we will think of as also quoted in potatoes. We will denote by $A$ the matrix whose columns are the $a^{j}$ 's, so that $A_{s, j}=a_{s}^{j}$. A portfolio for $A$ is $z \in \mathbb{R}^{J}$. The price of a portfolio $z$ is $q \cdot z$. It generates the cash (or potato) flow $A z$ : in state $s$, portfolio $z$ delivers $\sum_{j} A_{s, j} z_{j}$ potatoes.

Given a market with assets $A$ and prices $q$, a consumer with endowment $e$ will choose a portfolio $z \in \mathbb{R}^{J}$ to maximize her consumption $x=e+A z$, subject to $q \cdot z \leq 0$.

We say that a portfolio $z$ is an arbitrage opportunity if $q \cdot z \leq 0$ and $A z \geq 0, A z \neq 0$. Clearly, if there are arbitrage opportunities in the market then there is no solution to the consumer's problem, and any notion of equilibrium is precluded.

Theorem 20.1. Suppose that $A_{s, j} \geq 0$, and that for all $j$ there is an $s$ such that $A_{s, j}>0$. Then the following are equivalent:
(i) There are no arbitrage opportunities.
(ii) There is a $\mu \gg 0 \in \mathbb{R}^{S}$ such that $\mu A=q$.

Proof. Assume (i). We note first that $q \gg 0$, since if $q_{j} \leq 0$ then $z$ with $z_{j}=1, z_{k}=0$ for $k \neq j$ is an arbitrage opportunity. Consider the set

$$
V=\left\{A z \in \mathbb{R}^{S}: q \cdot z \leq 0\right\}
$$

This convex subset of $\mathbb{R}^{S}$ consists of all flows that can be achieved with a balanced budget portfolio, and thus $V \cap \mathbb{R}_{+}^{S}=\{0\}$. Hence, of we denote $\Delta_{S}=\left\{x \in \mathbb{R}_{+}^{S}: \sum_{s} x_{s}=1\right\}$, then $V \cap \Delta_{S}$ is empty. Since $\Delta_{S}$ is compact, by the separating hyperplane theorem there is a $\mu \neq 0$ such that $\mu \cdot x>0$ for all $x \in \Delta_{S}$ and $\mu \cdot v \leq 0$ for all $v \in V$. By the first property of $\mu$ we have that $\mu \gg 0$. The second property implies that $\mu \cdot v=0$ for all $v \in V_{0}=\left\{A z \in \mathbb{R}^{S}: q \cdot z=0\right\}$, since $V_{0} \subseteq V$ is a vector space. We thus have that $\mu A z=0$ whenever $q \cdot z=0$. So $\mu A$ is orthogonal to every vector in the space of vectors orthogonal to $q$, and hence must be equal to $q$, up to some constant $\lambda$. Since $\mu \gg 0$ and by our assumptions on $A, \mu A \gg 0$. Since $q \in \mathbb{R}_{+}^{S}, \lambda$ must be positive, and, by rescaling $\mu$, we have that $q=\mu A$.

Now suppose that (i) does not hold, so that that there is a portfolio $z$ with $q \cdot z \leq 0$ and $A z \in \Delta_{S}$. Then for any $\mu \gg 0$ it holds that $\mu A \gg 0$, and so

$$
\mu A z=(\mu A) \cdot z>0
$$

An implication of this result is that when there are no arbitrage opportunities, the price $q_{j}$ of asset $a^{j}$ is

$$
q_{j}=\mu \cdot a^{j}=\sum_{s} \mu_{s} a_{s}^{j} .
$$

So the price of every asset is a weighted average of what it delivers in the different states. As we note in the proof of the theorem, under the positivity assumptions on $A, q$ is positive. Since the consumers' problem is unchanged when $q$ is multiplied by a constant, we can assume that $\mu$ is in $\Delta_{S}$. So we can interpret it as a probability measure on the set of states, and hence each asset costs the expectation of what it delivers in the different states, according to this distribution.

We say that $A$ is complete if it has rank $S$.
Theorem 20.2. Suppose that $A_{s, j} \geq 0$, that for all $j$ there is an $s$ such that $A_{s, j}>0$. Then the following are equivalent:
(i) The market is complete.
(ii) There is a unique $\mu \in \mathbb{R}^{S}$ such that $\mu A=q$.

Proof. Suppose that the market is complete, so that $A$ has full rank. Then $v A=0$ implies $v=0$. It follows that if $\mu A=q$ and $\mu^{\prime} A=q$ then $\left(\mu-\mu^{\prime}\right) A=0$, and thus $\mu=\mu^{\prime}$. Conversely, if $A$ does not have full rank, then there is some $v \neq 0$ such that $v A=0$. Hence if $\mu A=q$ then also $(\mu+v) A=q$, and $\mu$ is not unique.
